AMCEBIC OR TROPICAL DYSENTERY: Its Complications & Treatment.

By W. CARNEGIE BROWN, M.D. Fcap 4to 271 + viii pp. Cloth. 7s 6d. net, postage 4d.

"For the practising physician the work cannot fail to prove of great service. We confidently recommend the volume to those who may be called upon to treat or prevent Amcebic Dysentery." — *The Lancet*

The book is well and clearly written and should prove a useful addition to the literature of this interesting and important subject." — *British Medical Journal*.

Dr. Brown's book should be read by all who have a special interest in this very important disease. "Medical Press and Circular" All interested will find it a most valuable work and since dysentery is so frequent in India we specially commend its pages to our practitioners." — *Indian Public Health and Medical Journal*.

"The book in its completeness and care of compilation reflects considerable credit on the writer." — *Midland Medical Journal*

83, 85, 87, 89 & 91, GREAT TITCHFIELD ST., OXFORD ST., LONDON, W.

The Cabendish Lecture

OR

THE FATE OF PATIENTS WHO HAVE HAD STONES REMOVED FROM THE KIDNEY

Delivered June 23rd, 1916,

By SIR JOHN BLAND-SUTTON, F R C S Eng,
SURGEON TO THE MIDDLESEX HOSPITAL.

MR PRESIDENT AND GENTLEMEN,—The fate of patients who have had stones removed from one or both kidneys is an important matter, and one on which little has been written. Most of what I have to say on this theme is based on my own experience. I saw Morris remove a stone from the kidney of a woman in the Middlesex Hospital in 1880. The operation is historical, it proved that a stone could be removed from the kidney and the patient survive. In the interval operations for renal calculi have made amazing progress. The detection of stone in the kidney or in the ureter has become an art. The introduction of radiography improved this branch of surgery. A good radiograph indicates the presence of stones, from their shadows the surgeon learns their number, size, and position. Cystoscopy furnishes facts about the condition of the ureters. Clinical chemistry affords information of the value of the renal function, microscopic and bacteriologic examination of the urine completes the clinical picture.

During the past 25 years surgeons have been intent on methods of diagnosis and technique. These are now complete. Errors in diagnosis are so unusual that patients willingly submit to surgical interference when it is certain that the kidney contains a stone. Many patients ask questions concerning the effect on life, and the expectancy of life, when a stone is taken out of the kidney. These questions are easily answered in terms favourable to the patient, but I am anxious for data on which to frame an opinion of the probable frequency of bilateral renal calculi, and on the expectancy of life when one kidney has been removed for calculous disease.

ON PEOPLE WHO LIVE WITH ONE KIDNEY

When the removal of a disorganised kidney is recommended the patient invariably asks "How shall I get on with one kidney?" The answer is simple. Many are born with one kidney and lead useful, energetic lives, attain old age, and die ignorant of the fact that they had only one kidney. Hundreds of men and women are living from whom surgeons have removed a kidney on account of stone. Many live unsuspecting that one of their kidneys has been insidiously destroyed by calculous disease. A man with one healthy kidney may live as long as another with two, but often his existence is precarious.

An actor, aged 40, noticed blood in his urine after an attack of severe pain in the right loin. An expert radiographer obtained a deep shadow from the left kidney, but none from the right. The stone in the left kidney was so big that I could feel it through the abdominal wall. The kidney being disorganised I concluded that the patient was "living with one kidney" and suspected, in spite of the radiographer's negative report, that the pelvis of the right kidney contained a small migratory stone. I decided to remove the left kidney through an incision in the linea semilunaris, as this enabled me to examine the right kidney and ureter, but failed to feel a stone. I removed the left kidney, it was a thin-walled sac containing pus and a large branched calculus (Fig 1). Within a month the patient left the nursing home for Margate. Shortly after reaching Margate he was seized with acute pain in the right loin and was unable to pass water. Four days later he came to London in a condition of anuria. A few hours after his arrival I exposed the right kidney by an incision in the loin, let out much urine and passed a guide down the ureter to the bladder. Next day the patient passed urine naturally, soon he became convalescent and returned to Margate. An X-ray examination showed that the guide I passed down the ureter had pushed a stone, the shape and size of a cherry stone into the bladder. Whilst at Margate the patient passed the stone during urination and sent it to me in a

pill box. It is a curious form of retaliation that leads men and women to send renal calculi to surgeons in pill boxes.

My friend survived the operation six years. As a character actor he won approbation, like Yorick, he was "a fellow of infinite jest, of most excellent fancy." One evening, whilst waiting for his cue, he was seized with acute abdominal pain and seemed about to die. He was conveyed to a hospital hard by the theatre. A duodenal ulcer had perforated and a prompt operation failed to save him.

This case illustrates what most surgeons quickly learn from experience: a large disorganised kidney stuffed with calculi rarely disturbs a patient, but a small migratory calculus, no bigger than a cherry stone, in an otherwise normal kidney will render life unendurable by causing frequently recurring attacks of colic. Occasionally, the ureter of the less disorganised kidney is obstructed by one of these troublesome calculi, the patient becomes anuric and is brought, with dramatic suddenness, not only to the brink of, but actually into, the grave. The aphorism, *L'anurique est un individu qui la veille vivait avec un rein* (Legueu), though useful, does not apply to all anurics, for

FIG 1

A branched calculus removed from the kidney. Some of the branches broken during removal were placed together after the operation. This stone caused its owner no pain.

an individual may have two good kidneys and each harbour a stone. By an unusual concatenation of circumstances each ureter may be simultaneously blocked by a calculus. Many such occurrences have been recorded. Here is another.

A man, aged 44, weighing nearly 24 st, had suffered from attacks of renal colic and passed fragments of stone at intervals for 29 years. One night he was suddenly seized with acute pain in the right loin and became anuric. On the fifth day of the anuria he was admitted to the Middlesex Hospital and prepared for operation. When wheeled into the theatre he refused to submit to operation, urging that as he was now free from pain there could be no mischief. I saw him an hour later. He was intently reading the third chapter of the Lamentations of Jeremiah, in which the Jewish nation is personified as a man lamenting his own calamities. The following day he voided blood, became alarmed, and submitted to operation. I extracted a conical calculus from the upper end of the right ureter. Sixteen hours afterwards he had a slow pulse, muscular tremors, and contracted pupils. His mind remained clear almost to death which occurred 72 hours after the operation. At the post-mortem examination the left ureter was

found obstructed by a calculus of the same shape and size as that removed from the right kidney. This man died from simultaneous blocking of both ureters. The pelvis of the kidney were not much dilated, there was no sacculation, and the renal cortex showed little evidence of disease.

These two cases illustrate an important feature in regard to the "period of tolerance"—that is the time elapsing between the onset of anuria and the manifestation of uræmia. This is on an average six days. It is an axiom in renal surgery—*The earlier operation is undertaken after the onset of anuria, the better the results.* Thus the actor who submitted to nephrectomy on the fourth day recovered, the vacillating student of Jeremiah refused operation until the sixth day, and died, although from richness in renal tissue he had the better chance. A great danger besets men and women who have had a kidney removed for calculous disease. At any instant the ureter of the remaining kidney may be blocked by a stone.

In 1890 I removed from a fat cabman aged 38, the left kidney completely disorganised and crammed with stones. This man suffered no pain from his calculous kidney in spite of the fact that he daily jolted over the stones of London on a cab! Twenty five years later he was readmitted into the Middlesex Hospital with anuria of three days standing. Though this cabman was very fat, an oval swelling could be felt in the right loin. His kidney was exposed by means of an incision in the loin and the imprisoned urine released. Three days afterwards the patient passed water naturally, made a good recovery, resumed his work, and remains in good health.

The cabman and the actor may be usefully compared. Each lost a kidney, disorganised by calculous disease, and each had been "living on one kidney," as the phrase goes. Each ran risks of dying from anuria, and both were saved by a prompt operation, but the actor had his attack within two months of the removal of the kidney whereas for the cabman it was delayed a quarter of a century. The cabman is the longest survival after nephrectomy in my practice. He has been living for 26 years with one kidney, and now earns his living with a taxi cab.

Anuria is the gravest of the many complications of renal calculi. Its sudden onset, in persons apparently in good health, is a most impressive feature. In the early days of the anuria it is hard for them to realise that they are near death. Later, when the signs of uræmia appear, surgical interference is rarely successful. Spontaneous relief, due to the stone being extruded into the bladder, happens in about 25 per cent. Cystoscopy aids here. A cystoscopic examination sometimes reveals a calculus in process of extrusion through the vesical orifice of the ureter. I have seen such a delivery, it occupied two hours. The gradual advance of the stone with each pain was very striking. This is perhaps the nearest trial a man can have of the "pains of labour." With each "pain" the man uttered loud complaints. The preceding cases illustrate the varying attitudes of men to operative treatment, they vary with the phase of the disorder. When Shibli Bagarag rolled his body in the sand within sight of the city of Shagpat he exclaimed—

On different heads misfortunes come,
One bears them firm another faints,
While this one hangs them like a drum
Whereon to batter loud complaints.

A man in agony with a stone stuck in his ureter rolls about the bed, clamours for help—clamours loudly, shouts, and willingly submits to operation. When the colic is replaced by anuria, he disdains surgical interference and occasionally mocks at his advisers, but as soon as uræmia stalks anuria he passively submits to what is often a useless operation. Although the risks of an operation on the kidney with uræmia manifest are great it is useful like the barber Baba Mustapha to remember the poet's words—

The abyss is worth a leap however wide
When life sweet life is on the other side.

This is the position of a man stricken with uræmia the sequence of calculous anuria.

BILATERAL AND RECURRENT CALCULI

Having described examples of bilateral renal calculi in which the disease was advanced in one kidney and unoperated in the other we may now consider some in which both kidneys were known to be occupied with calculi. This is an important matter because surgeons hesitate to remove

bilateral calculi from fear of inducing uræmia, but there are conditions in which interference is justifiable. Watson collected 230 cases of renal calculi reported by six surgeons, he estimated that in 30 per cent of the patients stones were present in both kidneys. Among 100 patients under my own care stones were bilateral in ten. At my request Mr. W. A. Coldwell looked through his series of radiographs of calculous kidneys. Among 68 plates in which calculi were clearly shadowed and the stones subsequently removed, in eight the shadows were bilateral.

The risks of recurrence after nephro-lithotomy have never been estimated on a large statistical basis. It is difficult for a surgeon to calculate the proportion of recurrence even in his own practice. Patients have an idea that if a surgeon removes a stone from the kidney he is in some measure responsible if a new stone forms, and betakes himself to another hospital. There is another way in which recurrent renal calculi come under observation. A colleague retires, the patient comes again to the hospital, and is placed under the care of a successor or survivor. Here is an illustration. A woman, aged 28, came under my care with stones in a disorganised kidney. She had been submitted to nephro-lithotomy 12 years previously. I removed the kidney, in the drawing (Fig. 2) you will see the picture of the stone removed at the original lithotomy.

FIG. 2

kidney in section. Nephro-lithotomy had been performed on a lemon-shaped calculus removed in 1893. Twelve years later she came under observation with recurrent calculi. The kidney was removed.

It is probable that sepsis following nephro-lithotomy is in many cases responsible for recurrent calculi. For example, a woman had an enlarged kidney which a surgeon exposed and incised under the impression that it contained a stone. (Fig. 3.) Instead of a stone he found a narrow ureter, to remedy this a plastic operation was performed. The woman recovered without benefit. Two years later she came under my care, a radiograph showed a curious shadow low in the abdomen on a level with the iliac fossa. On the abdomen on a level with the iliac fossa. On exposing the kidney by means of an incision in the left linea semilunaris I found the pelvis distended with smooth urinary pebbles. I removed it. With the loss of the kidney the patient lost her aches and pains. It is reasonable to believe that the operation on the kidney led to infection and the formation of calculi. A renal calculus is a heap of crystals held together by cement substance. Thus after the kidney became infected crystals were precipitated from the urine and cemented by bacteria. Gall stones often contain a great clump of bacilli and have been reported to contain a great clump of bacilli and have been reported to contain a great clump of bacilli and have been reported to contain a great clump of bacilli. Gall stones are not renal calculi are tokens of pain and misery but poor problems.

of beauty and riches, are worn without any regard to the pain they may have caused the oysters I have had many renal calculi examined in the expectation of finding a clump of bacilli as a nucleus, so far without success. Micro-organisms are excreted by the kidney, and it is probable that the nucleus of a primary renal stone may be occasionally a clump of bacilli. Recurrent calculi are commonly associated with septic changes in the kidney in the infancy of nephro-lithotomy the operation was not carried out with the precautions and ritual which attend it to-day. A free incision was made in the cortex of the kidney, its pelvis and calyces were explored with a bare

FIG 3

Hydronephrosis associated with a narrow ureter. The pelvis is occupied by urinary pebbles.

and often septic finger. In many cases a rubber tube was introduced into the pelvis of the kidney for drainage, this provided a high road for an invasion by pyogenic organisms. *Bacillus coli* soon colonised the pelvis. When surgeons turned their attention to this matter it gradually became the habit in suitable cases to remove calculi through an incision in the pelvis of the kidney and carefully close the opening with sterile sutures. Primary union and speedy convalescence often follow with advantage to the patients, they recover quickly suffer less, and run less risk of a recurrent calculus. We must not lose sight of the fact that many calculous kidneys are septic at the time of the primary operation.

Calculi sometimes form in kidneys in an without the least evidence of sepsis. In 1900, aged 39, had signs of stone in his right kidney. graph showed such a large shadow as to make accuracy. During the removal of this surprise, on withdrawing it from containing the stones burst. In an area was covered with hundreds of iridescent calculi resembling little balls of burnished gold. We tried to pick them up, but they ran over the towels slipped between them dropped on the floor like hail and were as elusive as globules of quicksilver. The collected calculi to the number of 40,000, are preserved in the Museum of the Royal College of Surgeons. I saw this gardener in good health 12 years after the operation and still grateful for the relief the operation afforded him. The College Museum contains a similar specimen, the calculi number 27,000. They are of the shape, size, and colour of millet seed.

SURGICAL TIMIDITY

The conservation of a disorganised and septic kidney (Fig. 2 and 3) exposes patients to the risk of future suffering from recurrent calculi. This entails repeated operations and finally removal of the kidney under adverse conditions.

Endeavours to save such damaged kidneys are not examples of cautious surgery, but rather glaring instances of surgical timidity.

We are all more or less influenced by a wholesome respect for renal tissue. We know, too well, that some men get on in the world with very little brains, some with none. But no man can live without a certain amount of kidney. Some push this witicism too far. Many patients suffer much discomfort, even misery, from a timid nephrotomy when their best interests demand bold removal of the disorganised kidney. When a kidney is septic, calculous, and disorganised, if its companion is normal the diseased kidney should be removed. I have watched many patients, men and women, who have led rigorous lives after nephrectomy for calculous pyonephrosis.

It was my habit to give patients the stones I removed from their kidneys. A bad habit. The stones serve as souvenirs of discomfort and agony. Listen to a sufferer, an Italian poet—

Other white stones serve to mark happy days,
But mine do mark days full of pain and gloom
To build a palace, or a temple fair,
Stones should be used, but mine do serve
To wreck the fleshy temple of my soul.

Well do I know that death doth whet his glaive
Upon these stones, and that the marble white
That grows in me, is there to form my tomb.

(*Giri de Pers*)

These depressing lines represented at the time they were written the helpless condition of patients suffering from stone in the kidney. The natives of the southern part of America, at the time the continent was discovered, wore amulets of jade as a remedy for renal colic. This is how jade got from Spaniards the alternate name of nephrite. Fifty years ago in Europe the treatment of stone in the kidney had not got beyond the stage of physis. Amulets in another form, says the caustic critic.

ABSTRACT OF

In Address

OR

THE PREVENTION AND TREATMENT OF CHOLERA

Delivered before a Medical Conference in Malta,

By STAFFORD M COX, M.D. DUB.,
MAJOR ROYAL ARMY MEDICAL CORPS.

MR. PRESIDENT AND GENTLEMEN—If cholera visits Malta it will necessarily be seaborne. Local conditions are not favourable to the disease becoming endemic, but in a few days it could be a serious enemy.

Mass syringing with a cork (preferably only in mild cases) is a severe colla-
glass tubing 4 inches intestinal anti-
projection. The blanate of potash, much bene-
position by strapping. The extract
Nos 7 and 8 are pulants, such as interference with
essential. At least, such are useful result. Apart from
the absence of a pressure is under agreement with this
would be the best, it should be placed at a point easily
accessible and yet remote from road traffic. Fly proof cess-
pits and latrines open to the sunlight are essential. Quick
lime is recommended for these as the best drying and
disinfecting agent. In choosing a site the possible con-
tamination of existing wells should be remembered. A segre-
gation or detention camp in close relation to the hospital
will be needed for the isolation and disinfection of contacts.
Probably a week's detention after each fresh case would suffice.
In addition discharged contacts should have their addresses
registered, and for another week report daily at the hospital.
During the detention period each contact should be
immunised with Wright's prophylactic. Contacts becoming
cholera suspects should be placed in an observation tent
line. The same general measures with regard to latrines
and cesspits should be observed. A special form of
transport, preferably motor, should be provided for the
patients.

In the event of an actual outbreak the guard on reservoirs, should be strengthened, all wells, ships' tanks, &c., should be treated with permanganate of potash. Advisory circulars should be issued to both the military and civil population concerning what to eat and what to avoid. Aerated water factories should be officially supervised, and instructions issued generally for the regular testing and cleansing of filters. In the presence of an epidemic it is questionable if filtration alone is sufficient against this water borne disease. A defective filter is worse than none, and in my experience 20 per cent of the portable filter cores marketed are defective. Bacteriological examination of the water supply from the reservoirs and wells should be regularly made. Freshly isolated bacilli show the most typical morphology. Subcultures often show rod and coccoid forms due to medium reaction. Cholera red is often obtained with difficulty. Pure 24 hours' subcultures give best results. It is by immune reactions cholera is best identified.

TREATMENT

There is little hope of treating the fully developed disease by a bactericidal serum. I used the Pasteur serum in the intravenous infusion in 1907 in 24 cases with a mortality rate of 33 per cent, as compared with 28 per cent for 65 cases where the saline alone was used. This was probably accidental—the number of cases was too small to indicate more than that, exceptional advantages are not to be expected from its use. Doubtless bactericidal sera when employed in other acute diseases are considerably helped by the body cells in the elaboration and neutralisation of toxins. In the collapse stage of cholera the circulatory derangement is so great and the body resources are so exhausted that little help can be expected from the patient's tissues. Serum treatment, therefore, would seem to be contra indicated as likely to hasten the breaking up of the vibrios, the evolution of their endotoxins, and a speedier intoxication in the absence of assistance from the body cells. All attempts to produce a potent antitoxic serum have so far failed owing to the difficulty experienced in procuring the corresponding circulant toxin.

The best hope of combating the disease from this point of view is therefore in the prophylactic treatment, by inducing an active immunity sufficient to destroy the bacteria that enter the body before they have time to increase. Mild infections will probably be fully met by this means, but severe primary infections will still probably show the incompleteness of the immunity given. Three forms of prophylactic inoculation have been chiefly used. Haffkine uses the living cultures in two injections of two strengths, giving immunity in ten days. The severe local reaction is the main objection to its use. Protection is supposed to be in proportion to the reaction. Strong employs an autolysate. It produces no reaction. 2-5 c.c. are usually given, but mass doses can be used. Wright's prophylactic inoculation also produces no appreciable reaction. 150,000 of the Serbian troops have been inoculated by the Royal Army Medical Corps with this prophylactic without accident.

Treatment solely by medicine is inadmissible in incipient cases. The drugs most in use are antiseptics, such as urotropin drinks, permanganate mild, castor oil, and chloroform. Cardiac stimulant and digitalin and pituitary body. Saline drenches, such as Morphine should not be given if the blood pressure is under 100 mm.

TREATMENT OF COLLAPSE STAGE OF CHOLERA

The chief conditions indicating treatment are (a) Lowered blood pressure, normally 120-130 mm. this may fall to 50 or 60 mm., causing a cessation of kidney function. (b) Concentration of blood. The normal specific gravity of 1055 may rise to 1080. This would correspond to a loss of about two thirds of the fluid constituents. The blood becomes tarry and circulates with difficulty. (c) Loss of vaso motor control of capillaries, especially in the intestinal canal attributed to absorption of the endotoxins. A drainage of the blood fluid into the intestinal canal is thus set up, forming the characteristic rice water stools and vomit. (d) Cardiac angina and cyanosis. (e) Great loss of body heat. The temperature in the axilla or mouth varies from 95° to 97° F., being usually somewhat higher in the rectum. The extremities fall to practically the temperature of the surroundings, the patient is chilled to the bones. The skin becomes as

plastic as that of a corpse, retaining for some considerable time the shape given by pinching it.

I draw particular attention to this great backward swing of the pendulum of body heat, which in the nature of things if the patient recovers, we would expect to be followed by an almost equally marked forward oscillation, with all the phenomena of returning animation, as is seen in other allied conditions of chill. Spontaneous reaction from this extreme condition is rare, and if it occurs is associated with pyrexia of a more or less continuous type, forming the group of symptoms classified as the stage of febrile reaction. Happily, intravenous saline transfusion produces an adequate reaction without these features. It is found that when about 5 pints of fluid have been infused the patient—who has then lost his cramps, has had his pulse restored, and perhaps shows a temperature of 100°—invariably develops a rigor proportionate in severity to the degree of collapse, the patient's teeth rattle like castanets, he is seemingly extremely ill, and an inexperienced attendant would probably stop the transfusion.

To divert for a moment, Rogers, in his most excellent work on cholera, rallies me for the use of hot-water bottles in cholera, and states he has banished them from his wards. His statement is quite correct. I use hot water bottles and even extra blankets, but only for the ten minutes occupied by this stage of transfusion rigor, through which all patients adequately treated with saline must pass. I have most carefully read his work on cholera and can find no description whatever of his patients having "transfusion rigors." If they have no rigors I can understand their not needing hot-water bottles. I regard this condition as all essential, and should it, as sometimes happens, be delayed through the solution running cold or a kink in the tube stopping the flow impaired results must be expected. The average amount of saline transfused by Rogers is 4 pints, in exceptional cases 5 pints, this just falls short of the amount which produces the reaction rigor, and the presumption is that Rogers does not carry his transfusion to this point, has not seen the reaction rigor, and therefore does not use hot-water bottles. The comparatively moderate results he has obtained using means that practically correspond in kind, but not in degree of use would seem to confirm this explanation. They are as follows: his are taken from his work on cholera using hypertonic saline, mine were obtained using isotonic saline.

India	China
Rogers, 1910 and part 1909	Cox 1909
Collapse stage cases only	Collapse stage cases only
Number of cases, 103	Number of cases 666
Average amount transfused, 4½ pints	Average amount transfused 13 pints
Mortality, 32 per cent	Mortality 18.5 per cent

In this connexion an interesting point remains to be noticed. Rogers strongly denounces the employment of opium in any form in cholera and has never seen any but ill results from it. This, again seems due to inacquaintance with the transfusion reaction rigor, the indications for its employment are then most manifest. I have found for it a beneficial effect in cases once they pass the stage of rigor. The blood pressure is then rising rapidly and interference with the kidney function has never been seen to its use in this respect I am quite in agreement with the high authority that it is contra indicated.

The proportionately greater loss of body chlorides in the stools of severely collapsed cases pointed out by Rogers induced me in 1913 and 1914 to use hypertonic strength with a proportionate decrease in the amount of fluid. In some 45 cases I used an average of 8½ pints of hypertonic solution with good results. I found that this procedure lessened the tendency to relapse. Hypertonic strength should therefore be used in preference to isotonic until an average amount of 7 to 8 pints for adults has been introduced, after that if more fluid is required isotonic should be used. The fluid necessary is estimated by the blood pressure and specific gravity.

WORKING NOTES

Few medical procedures show a more striking correspondence between the care exercised and the results attained than intravenous infusion in cholera and this is the only apology offered for the perhaps over elaboration of details which

follow As the collapse stage is the most important phase of the disease and the only one requiring this treatment, that stage only will be dealt with

My acquaintance with the disease was gained at Shanghai, where since 1907 I had charge of the Chinese cholera hospital, and have treated over 2000 cases I used an apparatus devised by R H Cox, F R C S, by which a solution of saline in boiled water is led to the vein through a filter placed in circuit and is maintained at the temperature desired by an adjustable heat-regulating mechanism Sir Leonard Rogers uses an apparatus consisting of a cistern, tubing, and a stopcock for regulating the flow, through which he introduces 4-5 pints of hypertonic saline in distilled water in 20 minutes The chief disadvantage in this method lies in the difficulty in procuring freshly distilled water, except in times of peace or at a base Apart from this, the rate of flow indicated is too quick per minute, except in the first two pints, in severely collapsed patients The quantity (4-5 pints) is also insufficient to induce the reaction rigor

The advantages of the method of continuous intravenous saline infusion are 1. A regulated flow at a constant temperature can be maintained 2. Boiled water, an easily procurable commodity, is used 3. A considerable number of cases can be maintained running at the same time, the apparatus being self regulating requires little attention 4. The rate of flow is more gradual than that used by Sir Leonard Rogers (approximately 2 ounces per minute) and the transfusion lasts (approximately) 1½ hours Less bodily disturbances

FIG 1

Earlier form of transfusion apparatus taken from a Report on an Outbreak of Asiatic Cholera in Shanghai during the Summer of 1907 by Stafford M Cox M D (Methodist Publishing House Shanghai 1907) a Glass cistern b Metal stand consisting of two compartments—c a chamber for the spirit lamp and d water bath for cistern e Spirit lamp f Reservoir of saline n Feed tube from reservoir to cistern.

and a more permanent condition of reaction result 5. The reaction rigor is obtained 1. A detailed description of the apparatus is omitted, as apart from the sets (40) provided for the use of the writer it is not available. The illustrations given (Figs 1 and 2) depict an earlier form of the apparatus but the essential features apart from the heat regulating apparatus can be readily improvised and the procedure and requirements for doing so will now be detailed

Requirements

1 A Berkefeld filter candle (the type used in the Berkefeld travelling pump) Efficient English substitutes of similar size are now procurable 2 A wide mouthed jar (preferably of glass) as a reservoir with a capacity of 4-5 pints 3 2½ yards of rubber tubing—viz an upper length of 1 yard and a lower of 1½ yards, joined either by a piece of glass tubing which will serve as an observation tube for bubbles or a glass bubble-catcher 4 A glass cannula made with a bulbous neck giving secure invagination in veins of different calibre, and with a fine point to facilitate

FIG 2

The glass cistern on a larger scale. f g Temperature regulating mechanism f Berkefeld filter candle. k Position of glass bubble-catcher or of observation tube. l Glass cannula for insertion into vein

entry This can readily be drawn in a spirit flame 5 A bath thermometer taken from its wooden case and allowed to float in the reservoir 6 Some 10-12 bottles (peroxide of hydrogen type) with glass stoppers and wire fittings, to be ready filled with hypertonic saline (1.33 per cent), 6 with hot and 6 with cold saline 7 A Berkefeld travelling pump (similar sized English can now be obtained) 8 If a bubble-catcher is used it will replace the observation tube joining the rubber lengths It can easily be made from a small glass syringe by removing the piston and replacing it with a cork (preferably of rubber) pierced with a piece of glass tubing 4 inches long with an equal inside and outside projection The bubble-catcher must be held in a vertical position by strapping during infusion

Nos 7 and 8 are recommended if available, but are not essential At least 20 per cent of candles show faults In the absence of a bacteriological examination of filtrate the candle should be tested by blowing through a short rubber attachment into the emptied and damped chamber whilst submerged in water Small faults, shown by a stream of bubbles can be closed with cement or plaster of Paris

Sterilising often causes faults and should be started at a moderate temperature using a tray A good effective sterilisation can be made by placing the candle in a Berkefeld travelling pump and driving a solution of hot permanganate of potash through If a steriliser or pump is not available the candle should be repeatedly filled and emptied with the same solution

Causes of ineffective flow are —1 Deposit of salt crystals Treatment Light brushing running through with Berkefeld pump in hot water 2 Lessening of filtration area from the presence of air in the inverted chamber Treatment Remove the cannula restore the candle to erect position in the reservoir, dislodge the air, reinvert and return cannula to the vein

The rubber tubing is best disinfected by boiling or syringing through with boiling solution of permanganate The connection should be secured with soft silk.

For a delivery into the vein at 99°-100° with summer heat conditions using a tubing 2½ yards long, a cistern elevation from the vein of 5 feet, and a cannula with a bore which gives 2 ounces of saline per minute in a jet 3-4 inches high, the temperature at which the cistern saline will require to be maintained will be found to be between 106°-108°.

As to the procedure for infusion, the filter candle (scrubbed, tested, and sterilised) is filled by hanging on the side of the elevated cistern (filled with saline at the appropriate temperature), the rubber tubing is then attached *in situ*, and the tube is milked till a current is established. All contained air is then removed by placing the candle slantwise bodily in the container and raising the tubing to form an upward curve, using both hands. As the right hand progresses with the air along the tube the left depresses the tubing emptied of air to prevent its return, and this procedure is continued till the uplifted cannula is reached. The candle is then inverted in the cistern and the apparatus is ready for use, if a bubble catcher is used inversion is not necessary.

Intravenous Infusion

An adequate reaction proportionate to the degree of collapse must be looked for and assisted. This condition is never attained until the infusion reaction rigor (which occurs approximately when 5 pints have been infused) is well passed. The continuance of the saline infusion after the occurrence of the reaction rigor up to 8-10 pints will procure the following benefits: 1 Dilution of the blood. 2 Elevation of the blood pressure, with re-establishment of suppressed renal flow. 3 Elimination of the endotoxins from the blood and later from the stools, thus obviating the onset of the febrile reaction stage of cholera, the remainder of the illness being usually apyrexial. No apprehension need be felt at a rise of temperature to 103° during the infusion, in fact, this degree of temperature oscillation I consider the most favourable for cessation of infusion, provided that more than 6 pints have passed in. If pyrexia of 103° is associated with the infusion of less than 6 pints, the temperature of the saline in the cistern should be lowered and the infusion continued.

Where the stools are sanious (a condition usually associated with a high rectal temperature) the saline should be infused at 98° or less, and 5 or 6 pints used. Such cases need a specially careful treatment, the associated dysenteric condition being only benefited indirectly by the relief of the collapse.

Strangely enough, I have found marked collapse when it is due solely to the loss of blood fluids a favourable index in prognosis as showing an absence of febrile complications and such cases, however profoundly collapsed, give excellent results. In such instances where the pulse is absent and death seems imminent, the rate of flow should be started at 4 ounces per minute until the pulse returns. If delivery of saline to this extent cannot be obtained by elevating the cistern and using a cannula of a wider bore a vein on the opposite side should be opened and fed from an additional candle which may be placed in the same container. On the return of the pulse to the wrist, one apparatus will be found sufficient to ensure reaction.

The associated conditions in this form of collapse are: (1) Marked plasticity of the skin, (2) great backward swing of the body heat as evidenced by icy chilliness of the extremities, an oral temperature of 95°-95½ and a rectal somewhat higher, (3) an unrecordable blood pressure, (4) a blood specific gravity in the neighbourhood of 1080, and (5) usually intense cramps. In such cases a marked rigor must be expected and hot water bottles and blankets held in readiness usually also a 1/40 grain of morphia with 1/100 grain of atropine hypodermically will be found useful after the rigor is passed.

The preparation of the vein selected is carried out in the usual way, no anæsthetic is necessary, the cannula is fixed in position by adhesive strapping the arm placed on a splint and secured to a bedstead in anticipation of the muscular movements caused by the reaction rigor. Straw palliasses and tin floor trays are advisable. If the hospital has a more or less permanent character a tin floored transfusion room is recommended.

That the reaction induced by saline transfusion may to some extent be due to a toxæmia induced by the endotoxins of water borne bacilli used in the infusion is possible, that it entirely accounts for the reaction rigor I do not believe. In any case it will be interesting to see to what extent the phenomena of the infusion reaction will be modified by filtration previous to boiling.

REMARKS ON THE CAUSE AND NATURE OF THE CHANGES WHICH OCCUR IN MUSCLE AFTER NERVE SECTION

By J N LANGLEY, ScD FRS,
PROFESSOR OF PHYSIOLOGY, CAMBRIDGE.

Two theories have been put forward to account for the obvious fact that section of a nerve causes trophic—i.e., nutritive—changes in the muscle it supplies. One is that there are special nervous impulses affecting nutrition different from those causing contraction. Since there is no independent evidence of the existence of such impulses, this theory has received little support. The other is that the maintenance of the nutritive condition of the muscle depends upon its contracting at intervals, so that when the normally occurring contractions are prevented by nerve section the nutritive condition of the muscle suffers, and it gradually loses weight and decreases in irritability. This theory has in its favour the fact that normally the size of muscles is, within certain limits, dependent upon exercise. In accordance with it the wasting of denervated muscle is spoken of as “disuse atrophy,” and largely on the basis of this theory it is a common practice to induce contraction in paralysed muscles by stimulating them with condenser or galvanic currents. If this theory were true a certain degree of contraction brought about by electrical stimulation would keep the denervated muscles in a normal condition. It need hardly be said that this never occurs in clinical practice. In man the degree to which electrical stimulation prevents wasting of the muscles cannot be determined with any accuracy. A few experiments on this point were recently made on rabbits by Professor Kato and myself.¹ The tibial or peroneal nerves were cut on both sides and the paralysed muscles stimulated on one side with condenser current. Taking the weight of the muscles on the unstimulated side as a standard the percentage gain in weight on the stimulated side in the four experiments made was 18 days, 0, 28 days, 22.9 per cent, 36 days, 9.8 per cent, 71 days, 10.3 per cent. These experiments, whilst suggesting that contraction delayed the wasting of the muscles, were not definitely in favour of the theory of “disuse atrophy” for in each experiment great wasting of the muscles occurred and the sluggish response to electrical stimulation characteristic of denervated muscle was not prevented. Further the difference in weight on the two sides might possibly be due to individual variation, and I have elsewhere found variations up to about 7 per cent in the weight of the muscles on the two sides in normal rabbits.² In the experiments mentioned above the extent of daily stimulation was not the same in the several experiments. It varied from less than to about that usually applied in cases of man. The absence of decisive delay of atrophy might then be due to the degree of stimulation being insufficient. I have in consequence made two further experiments on rabbits. In one stimulating for about 2½ hours a day for rather more than three weeks and in the other extending and flexing the limb for a like period. In neither case was there any certain delay in the wasting of the muscles.

Since, then, contraction of the muscles neither for a short daily period nor for a long daily period prevents the wasting of the muscles nor the occurrence of sluggish contraction, I conclude that the changes which take place in muscles after nerve sections are not due to absence of contraction and that the term “disuse atrophy” is a misnomer. In this case we have to look for some other cause of the atrophic and other degenerative changes. It was noticed by Professor Kato and myself that muscles from about the fourth day after section of their nerves are in a state of continuous fibrillation—i.e. the separate muscle fibres contract rhythmically but with different rhythms, the muscles present a shimmering appearance when viewed by light reflected from the surface. The contractions cause no movement of the muscle as a whole.

¹ Journal of Physiology, 41, 1915, p. 101.
² It may be mentioned that I have very rarely (perhaps never) seen any signs of previous injuries. This is in a case in which the tibial nerve on the left was the last to be cut, and the peroneal side was less than that on the right. I have also examined the fibrous tissue of the lower limb after section of the lower limb at a point below the knee joint, and in consequence had no direct observation of the nerve.

and are easily overlooked, possibly they could be shown in man by the use of the string galvanometer. As each fibre contracts many times a minute the total expenditure of energy in the day must be considerable. It is, then, I think, reasonable to suppose that this continued activity of the muscle fibres must cause fatigue and that the atrophy of muscle is due to too great rather than to too little functional activity. The changes in reaction which occur in denervated muscle are, in fact like those caused by fatigue. I have, however, not found any definite evidence that the stimulation is harmful. With regard to this, it has to be borne in mind that contraction drives on lymph and tends to prevent the accumulation of metabolic products. It may also cause an after increase of the blood flow, and in the later stages of paralysis at any rate when the blood-vessels have recovered tone, this would no doubt be beneficial. But on the whole it appears to me probable that it would be better to obtain these accessory results of contraction without the contraction itself. And in the recent discussion on Dr F. Herniman-Johnson's paper on the use of condensers in the treatment of nerve lesions, Dr E. P. Cumberbatch states that he has obtained good results by the use of sinusoidal alternating currents not causing contraction.

There are two points I would comment on with regard to the reaction of denervated muscle to electrical stimulation.

1. Cases were early noticed in man in which, after nerve severance, voluntary power may return before the response to faradic currents, and in the recent use of condenser currents it has been found that voluntary power may return without a return of response to condenser shocks of short duration.

It has long been known that in the early stage of regeneration tetanising currents applied above the point where the ends of the severed nerve were united will cause contraction whilst similar currents applied below it have no, or less effect. Some instances of this in the limb nerves are given by Howell and Huber,⁴ together with earlier references, and I have found a similar condition after joining the vagus to the cervical sympathetic.⁵ The result has been spoken of as showing that nerve fibres in regeneration recover conductivity before irritability. The difference is probably one of difference of response to currents of different duration and to this may be attributed the return of voluntary power before return of response to currents of short duration.

2. The fact that faradic currents as applied in testing the reaction of muscles in man cease to cause contraction four to seven days after nerve severance, whilst recognised as partly due to the disappearance of nerve irritability is often taken as showing that the muscle fibres themselves have lost their irritability to faradic currents. In support of this view it has been urged that in animals the effect of the nerves may be abolished by curari without abolishing the faradic irritability of the muscles so that in man the disappearance of the latter must be due to a change in the muscles. But several observers have noted response to faradic stimulation in the exposed muscles of animals several weeks at any rate, after denervation, and I have obtained it in the exposed muscles of the rabbit at all times up to 10 weeks the longest period I have tried. In consequence I should attribute the absence of response which occurs in man to the currents employed being too weak.

I have not made sufficient experiments to be certain of the progress of decrease of irritability to induced currents in denervated muscle but so far as my experiments go it is slow and gradual. In lower vertebrates the irritability of muscle fibres is greater in the region near the nerve-ending—the neural region—than in other parts of the fibre and no doubt the same is the case in the mammal. In this case the extent of the contraction on stimulating the denervated muscle directly will depend on the position of the electrode with regard to the neural regions of the muscle fibres. In general most of the neural regions lie in an oblique band somewhere near the middle of the muscle and are absent in the end portions.

It is possible that a sudden drop of irritability occurs in the neural region in the later stages of denervation, I have not noticed this in my experiments but some recent observations of Professor Noel Paton and Dr L. Firding⁶ suggest its occurrence when galvanic currents are used.

THE DIAGNOSIS OF CANCER OF THE STOMACH¹

By JAMES ALEXANDER LINDSAY M.D. R.U.I.,
F.R.C.P. LOND.

PROFESSOR OF MEDICINE IN THE QUEEN'S UNIVERSITY OF BELFAST

CANCER of the stomach is from several points of view one of the most important conditions which claim our attention. It is important from its frequency. The stomach comes next to the uterus as the seat of cancer. Cancer of the stomach accounts for 1.5 per cent. of all deaths occurring in hospital practice. It is important because early diagnosis is often a matter of extreme difficulty and also of the greatest importance, if operative intervention is to have any fair prospect of success. It is important, finally, because to suggest to a patient an unfounded suspicion of cancer is one of the most serious and unfortunate of errors.

During the last 14 years 40 cases of cancer of the stomach have occurred in my practice at the Royal Victoria Hospital. I am much indebted to my assistant, Dr S. I. Tarkington, for the careful manner in which he has collected and collated this material for me. I shall confine myself to the diagnostic problem, leaving the question of operative measures in the very capable hands of Mr A. B. Mitchell.

1. *Age of patients*.—No case occurred under 30 years of age. Fourth decade 5 cases 12½ per cent., fifth decade, 7 cases, 17½ per cent., sixth decade, 19 cases, 47½ per cent., seventh decade, 8 cases 20 per cent., over 70, 1 case 2½ per cent. These figures are in accord with general experience. The disease falls mainly upon the fifth, sixth, and seventh decades of life with a slight preponderance in the sixth decade. Cases are not unknown in earlier life. The disease is not rare at advanced ages.

2. *Sex*.—Males, 23, females, 17. Most observers report a preponderance in the male sex. The proportion is usually given as 5 to 4 which is in close correspondence with my own figures. Some authorities report a considerably higher proportion of males while Fenwick thinks that the sexes suffer equally. The Registrar General's Reports for England and Wales (1901-1909) show that in males cancer of the stomach accounts for 21.4 per cent. of all deaths from cancer, but in females the figure is only 14.2.

3. *Family history*.—There was a clear family history of cancer in 4 cases—i.e., in 10 per cent. In a fifth case there was a history of doubtful 'gastric disease'. One woman stated that her husband had died of cancer. In the remaining 34 cases the family history was unimportant.

4. *Personal history*.—A history of previous gastric ulcer was obtained in only 5 cases—i.e., 12½ per cent. There is a curious almost disconcerting discrepancy between physicians and surgeons as to the frequency with which simple gastric ulcer precedes gastric cancer. Habershon found this sequence in only 5 cases out of 340. Fenwick puts the proportion at 3 per cent. Osler found the sequence in 4 cases out of 150. On the other hand Mayo puts the proportion at 54 per cent. and Mornihan at 72 per cent. This is a very important matter from several points of view. If the higher figures are correct we shall be compelled to regard the remote dangers of gastric ulcer much more seriously than we have hitherto done. Further physicians have been in the habit of regarding the comparatively abrupt development of painful dyspepsia after the age of 40 as one of the most significant indications of commencing gastric cancer. It is evident that if simple ulcer is a common antecedent of gastric cancer this rule will fall to pieces. It is not easy to reconcile the higher figures with the preponderance of cancer in the male sex, nor with the marked contrast between the results of the examination of the gastric contents in the two conditions. My figures support the views of Habershon, Fenwick, and Osler.

Four patients gave a history of alcoholic excess. Osler found this history in 8 cases out of 150. There is no reason to conclude that alcoholism is a factor in the causation of gastric cancer.

In 25 out of my 40 cases the previous digestion of the patients was reported to be good.

5. *Mode of onset and initial symptoms*.—"Signal symptoms"

¹ Introduction to a recent discussion at the Ulster Medical Society.

⁴ Proc. Roy. Soc. Med. Surgical Sect., 1915, p. 1. THE LANCET, Feb. 1, 1915, p. 151. ⁵ Journal of Pathology, xiii, p. 324, 1912. ⁶ LANCET, p. 25, 1917. ⁷ LANCET, p. 153, 1916.

or symptoms"—i.e., symptom or symptoms which first attracted the patient's attention

(a) Painful dyspepsia	15 cases	37½ per cent
(b) Vomiting and pyrosis	9 "	22½ "
(c) Loss of weight	6 "	15 "
(d) Progressive weakness and anæmia	4 "	10 "
(e) Hæmatemesis	3 "	7½ "
(f) Anorexia	2 "	5 "
(g) Melæna	1 "	2½ "

This table is important, as in practically every case of gastric cancer symptoms precede signs, and early diagnosis is dependent mainly upon symptoms.

Painful dyspepsia was the earliest initial symptom in the largest group of cases, and this is in accord with general experience. The pain is less severe than in simple ulcer, it is less definitely referred to the epigastrium or the back, it tends to radiate towards the hypochondria, its relation to the ingestion of food is less close, local tenderness is, upon the whole, less marked and less definitely localised, if vomiting ensues the relief of pain is less complete than in simple ulcer. Hale White's rule is valuable—"Painful dyspepsia arising for the first time in a patient over 40 should lead to inquiry for gastric cancer." Constipation is the almost invariable rule in these cases.

Vomiting and pyrosis marked the onset in the next largest group of cases—9 cases out of 40. When occurring early in the disease, these symptoms may depend upon gastric catarrh; when occurring later they suggest interference with gastric motility, and their time relation to the ingestion of food depends upon the seat of the growth, being earlier in cancer of the cardia, later in pyloric growths. The vomited matter may be mucous, watery, rarely bilious, often offensive. Blood is present in the vomit in 42 per cent of cases, according to Brunton. It may take the form of "occult blood."

In 6 cases out of the series the first symptom to attract attention was an unexplained loss of weight. Careful weighing is a matter of the first importance when the presence of gastric cancer is suspected. The weights on admission in my series of cases were as follows: Under 6 st., 3 cases, 6 to 7 st., 5, 7 to 8 st., 8, 8 to 9 st., 8, 9 to 10 st., 8, 10 to 11 st., 2, over 11 st., 1, no record, 5. Of the 6 cases where loss of weight was the "signal symptom," 2 had lost 3 st., 1 had lost 2 st., and the remaining 3 had lost smaller amounts. Sixteen cases gained weight while under treatment, of whom 5 gained 1 lb., 4 gained 2 lb., 1 gained 3 lb., 3 gained 4 lb., 2 gained 6 lb., and 1 gained 10 lb.

In 4 cases—10 per cent—the earliest symptoms were progressive weakness and anæmia. This is an important group, as in it the difficulties of diagnosis are often at a maximum. Pronounced blood changes are usually late in the disease, but in an important minority of cases anæmia may be early and marked. The red cells may fall to one and a half millions or less, poikilocytosis may be pronounced, and microblasts and megaloblasts may be present. The distinction from pernicious anæmia may be difficult, or even for a time impossible.

In 3 cases—i.e., in 7½ per cent—hæmatemesis was the first symptom to attract attention. This is unusual but, as already stated, its occurrence at some stage of the disease is common. Brunton says 42 per cent., Boas 36 per cent. The amount of blood lost is rarely large. A free hæmorrhage speaks for ulcer rather than for cancer.

Anorexia was noted as the "signal symptom" in only 2 cases of the series. It is probable that the hospital records or the memory of the patients was in error on this point. General experience testifies that a somewhat abrupt failure of appetite, especially for flesh foods, is common in gastric cancer, and that its diagnostic importance is considerable. It is, of course, important to exclude other possible explanations of the anorexia of which alcoholism, avowed or secret, is one of the most common.

In only 1 case in the series was the patient's attention first arrested by an attack of melæna. It is probably quite rare as an initial symptom. Later in the disease melæna often in the form of "occult blood," is common.

Pyrexia.—Some rise of temperature was noted in no less than 19 cases of the series—i.e., in nearly one-half. In 11 cases the temperature did not exceed 100° F. In 4 cases it ranged from 100° to 101°, in 3 cases from 101° to 102°, in 1 case it exceeded 102°. Osler noted pyrexia in 74 cases

out of 150—a proportion similar to my own. Boas reports a series in which pyrexia was present in 24.6 per cent. Fenwick found that two-thirds of his cases were afebrile. Habershon thinks that a subnormal temperature is the rule.

Examination of the gastric contents.—In a well established case of gastric cancer the gastric findings when a test meal is given, if not absolutely pathognomonic, are often characteristic and suggestive. The usual picture is as follows: (a) Evidence of gastric stasis, food being present in the stomach six or seven hours after the last meal, (b) free HCl absent or much reduced, (c) lactic butyric and valeric acids often present, (d) occult blood present in the stomach washings, and (e) the Oppler Boas bacillus present.

We need further information as to the gastric findings in early cases of gastric cancer. Too much reliance must not be placed upon the presence or absence of free HCl. Its absence or marked reduction is the rule, but the exceptions are numerous. In a series of 343 cases collected by Moynihan free HCl was absent in 89.7 per cent. Osler records its absence in 84 cases in a series of 94. Dieulafoy attaches much importance to this sign, but gives no figures. In my own series free HCl was absent in 71 per cent of cases tested. It must be borne in mind that free HCl is absent in many other conditions—e.g., chronic gastritis, gastric fibrosis, pernicious anæmia, and Addison's disease. Free HCl is said to be more frequently present in cases of gastric cancer where simple ulcer has been an antecedent than in cases where this history is wanting. The presence of lactic, butyric, and valeric acid, and of the Oppler Boas bacillus is evidence of fermentation, but has not necessarily any further significance. Dieulafoy is of opinion that the anachlorhydria of gastric cancer and of chronic gastritis can be distinguished by testing the ferments. Total disappearance of the pepsin and the rennin points to gastritis, disappearance of the pepsin alone points to cancer. The presence of cancer cells in the stomach washings has been reported, but this is unusual, and is improbable in early cases.

Presence of tumour.—A tumour was detected in 15 cases of my series—37½ per cent. Osler found a tumour in 115 cases out of 150. Brunton held that a tumour could be detected in 80 per cent of cases at some stage of the disease. Taylor says that a tumour is rarely to be detected during the first three or four months. Its value as a "signal symptom" is not great. Some good authorities hold that when a tumour can be detected the growth is no longer local, and that the time for a radical operation is past. This view is contested by Kocher and by Moynihan.

The seat of the tumour in gastric cancer is variable. It may be felt in the epigastric region, the umbilical region or in either hypochondrium. It is usually hard, tender, movable and often nodular. Its mobility varies with its seat. Pyloric tumours are the most movable. The tumour is occasionally visible on inspection.

Complications.—Enlargement of the liver was noted in 9 cases of the series. Enlargement of the supraclavicular glands was noted in only 1 case. Some observers attach much importance to this sign and find the enlargement much more frequent on the left side than on the right. Four patients in my series had albumin in the urine. One patient had pyuria. These features were probably accidental. No case of phlegmasia was recorded. Trousseau attached much weight to this complication as a help to diagnosis and Dieulafoy agrees with this view. Jaundice was not noted in any of my cases. It is rare at an early stage but may arise when the liver or the pancreas has become involved secondarily.

Let us now consider the general question of the diagnosis of gastric cancer in its earlier stages. The following are the chief points which will repay attention.

A History.—The most usual history as we have seen is that of painful dyspepsia setting in sometimes rather abruptly, and without assignable cause in a patient over 40 years of age whose digestion in most cases has been previously good. In the next most frequent group the early symptoms are those of gastric catarrh. In the third group in point of frequency the early symptoms are those of gradual failure of health progressive anæmia loss of weight with or without important blood changes. Exceptionally the blood changes arise early and may simulate pernicious anæmia. In a fourth group the history is that of a chronic faulid ulcer which has resisted treatment.

B Early symptoms—Loss of appetite may be early and marked, and may be the first symptom to attract attention. Often it develops gradually. It is usually a prominent feature in established cases but I have known the appetite to remain good until three months before death. The dyspepsia of gastric cancer has the following features. It is attended by discomfort and pain, sense of fullness in the epigastrium, nausea, sickness, eructations of offensive gases, and in most cases vomiting. These symptoms are at first related to the ingestion of food but at a later stage they become more or less constant. The vomit is grumous, offensive, and often contains blood, usually in small quantity. The nature of the gastric findings has been already considered. Definite melæna is rare but "occult blood" is often found in the faeces. In the later stages the dyspepsia is conditioned by disturbance of the gastric motility.

C Physical examination—In most early cases the results of physical examination will be negative. Tumour and signs of gastric thickening or dilatation belong to the developed disease.

D Differential diagnosis—In a case of doubt or difficulty the following conditions may require to be differentiated from gastric cancer: (a) Chronic gastritis, (b) non-malignant gastric ulcer, (c) non-malignant pyloric growth, (d) pernicious anaemia, (e) phthisis.

(a) *Chronic gastritis*—Here the symptoms will probably be of longer duration than in gastric cancer. Some cause for the symptoms such as dietetic error or alcoholism will usually be discovered. The loss of weight and the failure of the general health will probably be less marked, anaemia will be absent or slight. Treatment will usually effect speedy improvement.

(b) *Non-malignant gastric ulcer*—This is more common in youth and in the female sex. Pain is more violent and has a closer relation to the ingestion of food than in gastric cancer. Hemorrhage is often free, vomiting gives complete temporary relief to pain, hyperchlorhydria is the rule, localised tenderness in the epigastrium is common, the anaemia present is of the chlorotic type. Treatment will bring about speedy improvement.

(c) *Non-malignant pyloric growth*—History, symptoms, constitutional condition, blood conditions and an examination of the gastric contents may clear these cases up, but as exploration is now practically free from danger it may be freely resorted to when an exact diagnosis is urgent.

(d) *Pernicious anaemia*—In those exceptional cases of gastric cancer where a profound anaemia of pernicious type overshadows the gastric symptoms the difficulty of differential diagnosis may be great. The blood examination may be indecisive though a red blood-count of less than 2,000,000 is rare in gastric cancer common in pernicious anaemia. None of the figured elements are absolutely pathognomonic of pernicious anaemia. The lemon tint of skin so characteristic of pernicious anaemia is not unknown in gastric cancer. Wasting is more marked and more rapid in gastric cancer than in pernicious anaemia. Dyspeptic symptoms will probably be less marked in the latter disease and a course of arsenic will usually effect marked temporary improvement. It is a useful clinical rule not to make a final diagnosis of pernicious anaemia until we have weighed the possibility of gastric cancer.

(e) *Phthisis*—Very exceptionally difficulty may arise in the differentiation of incipient phthisis and early gastric cancer. Both diseases may set in with a vague failure of the general health, loss of weight, anaemia and asthenia, without definite localising symptoms. Dyspepsia is occasionally a prominent feature of incipient phthisis. A mild continuous pyrexia may be present in either disease. But the distinction is rarely difficult. Cough is not long delayed in commencing phthisis, there is usually decided acceleration of the pulse, night sweating or hæmoptysis may supervene. A careful examination of the chest may reveal characteristic signs, family history may give a hint. None of the various tuberculin tests can be relied upon in a doubtful case.

There is no royal road to the diagnosis of early gastric cancer. The difficulties are often great. But a careful review of all the facts of the case history and symptoms, unrecorded much weight and the full utilisation of all modern methods of inquiry will usually enable us to arrive

at a sound opinion. Time and the negative results of treatment are the final test.

One interesting question remains for consideration—Is cancer of the stomach on the increase? The Registrar-General's returns show that in 1897 the deaths from cancer of the stomach were Males, 135 per 1,000,000, females, 123 per 1,000,000. In 1910 the figures were Males, 185 per 1,000,000, females, 155 per 1,000,000. This represents an enormous increase, but it is a question how far it is real, how far only statistical. The problem of the increase of cancer, like that of the increase of insanity, is very complicated. How far more accurate diagnosis accounts for the increase in the cancer figures, how far the diminished mortality from tuberculosis and the higher average of longevity react upon the incidence of cancer are questions of great interest upon which we should welcome further information.

Belfast

ON A SUBSTITUTE FOR PEPTONE AND A STANDARD NUTRIENT MEDIUM FOR BACTERIOLOGICAL PURPOSES

Report to the Medical Research Committee

By SYDNEY W. COLE M.A.,

UNIVERSITY LECTURER IN MEDICAL CHEMISTRY, CAMBRIDGE

AND

H. ONSLOW

TRINITY COLLEGE, CAMBRIDGE.

(From the Biochemical Laboratory, Cambridge)

EVEN before the war the preparation of a standard broth for bacteriological purposes was a matter of considerable difficulty, since different samples of Witte's and other peptones exhibited such marked variations when employed in nutrient media that the cultural features of an organism were apt to vary with each sample used. Since the cessation of the supply from Germany this trouble has been accentuated and in work that we have been doing for the Medical Research Committee on the differentiation of the members of the colon typhoid group we have felt it acutely, because the results obtained when a given sample of peptone is used cannot be repeated with certainty with another sample. This is, in truth, readily explained—"Peptone" is no more than a name which may stand for widely varying substances. Usually it consists of a mixture of proteoses, peptones and polypeptides which differ enormously both in complexity and amount according to the materials employed, the length of digestion allowed, and the exact method of preparation followed.

Now it is probable that non-proteolytic organisms cannot utilise the higher proteins as food substances and that even the proteolytic organisms grow more readily at first in media which contain an adequate supply of immediately available food material. The nitrogenous substances used by the growing organism are in all probability mainly free amino-acids together with small amounts of other substances that have not as yet been determined.

In the work that we are conducting we have found a sharp criterion for a standard nutrient medium. If a medium containing a fermentable carbohydrate be sown with a specific organism a definite final hydrogen ion concentration is reached. This is dependent in a remarkable degree upon the constitution of the fluid, a very slight change in which may cause a considerable variation in acidity. This effect is most clearly seen if more than one organism be employed. In fact we have often noticed that the degrees of acidity produced by two organisms may actually be inverted.

With these views and facts before us experiments were made with various media containing an abundant supply of these amino-acids. The growth on such media of a large number of pathogenic organisms is so rapid compared with their growth on the recognised standard media that we think it desirable to publish the method of preparation in the hope that it may be of general value as a cheap and effective substitute for peptone and nutrient broths. We also describe a simple method of standardising the reaction of media the

usual laboratory practice of titrating against litmus or phenolphthalein being extremely unsatisfactory.

The supply of free amino acids is best obtained by the tryptic digestion of casein, and to procure uniform results a pancreatic extract is used, prepared by a method that has for some time been employed in our laboratory, and which follows a formula given by Mellanby and Woolley. It is true that this preparation is not a standard one, because the proteolytic activity varies in a way that cannot be controlled. We have thought it undesirable to complicate the technique by a preliminary standardisation of the tryptic value of the extract, but with the amounts of ferment and the length of digestion used we think that a sufficient degree of hydrolysis is reached to give practically uniform results.

The details of the preparation of the pancreatic extract, the tryptic broth, and the method of standardisation are as follows—

Pancreatic extract—Obtain the fresh pancreas of a pig, free it from fat as far as possible, and weigh. Mince it finely and add three times its weight of distilled water and its own weight of strong alcohol. Shake well in a large bottle and allow it to stand for three days at room temperature, shaking the bottle occasionally. Strain through muslin and filter through a large folded paper. The filtrate, which comes through very slowly, is measured and treated with 1 c.c. of concentrated hydrochloric acid for every litre. This causes the appearance of a cloudy precipitate which settles in a few days and can be filtered off. The fluid keeps for an indefinite period if stoppered, without any additional anti-septic. If desired at once the extract may be used before adding the hydrochloric acid the function of which is to retard the slow auto-destruction of the trypsin.

Digestion of the casein—We have tried various commercial preparations, and have finally decided to employ a product made by "Casein, Limited." This is prepared by a standard method yielding a product which in our experience is practically uniform and remarkably free from carbohydrates and free alkali. The firm has consented to supply the material under the name of "Laitprote, No. 6 for bacteriological purposes." To 1 litre of tap water add 20 gm. of anhydrous sodium carbonate and boil in a 2 litre flask or large evaporating basin. When boiling transfer the vessel to a boiling water bath and gradually add 200 gm. of the casein. This must be "dusted" in carefully and well stirred to avoid the formation of lumps. Transfer to a Winchester quart and wash out the mixing vessel with a litre of cold tap water, which is also transferred to the bottle. If necessary, allow the temperature to fall to 40° C. and add 50 c.c. of the pancreatic extract and 15 c.c. of chloroform. Shake well, stopper with a loose cork, and incubate at a temperature of 37° to 40° C., shaking the bottle vigorously each day to break up any lumps. After five days' digestion add another 50 c.c. of the pancreatic extract and allow the mixture to stand for another 10 days—that is, not less than 15 days' digestion in all.

Preparation of the stock broth—The warm mixture is well shaken to break up any crusts of tyrosine that may have formed, and is transferred to a large (3-litre) flask, treated with 400 c.c. of normal HCl (or 40 c.c. of pure concentrated HCl diluted with 360 c.c. of water) shaken, steamed for 30 minutes, and filtered. The filtrate is treated with 120 c.c. of normal sodium hydroxide and the reaction adjusted.

Preparation of tryptic broth—The stock broth is diluted with twice its volume of 0.5 per cent sodium chloride dissolved in tap water and the reaction is adjusted.

Adjustment of the reaction—It is now well known that the most significant point in the standardisation of media is a constancy in the hydrogen ion concentration. This cannot be obtained by the ordinary methods of titration. It may be found accurately by "electric titration," but this method is too complicated for routine work. A very close approximation is reached by following Sorenson's procedure of colorimetric comparison. The principle of this method is that when a given amount of a suitable indicator is added to a given volume of two fluids the colours produced are identical if the hydrogen ion concentration of these two fluids is the same. This is subject to certain qualifications, since the colour produced with some indicators is affected by the constituents of the fluid.

For standardisation of the broth a hydrogen ion concentration was chosen of about $P_H = 7.35$ (i.e., a concentration of

hydrogen ions per litre of 10^{-7} or 4.47×10^{-8}). This is a reaction very near to that of blood serum and also near the optimum for the growth of most pathogenic organisms.

Our method of standardisation is based on Walpole's principle of eliminating the colour of the broth by use of a special tintometer. This procedure was modified by Hurwitz, Meyer, and Ostenberg. We think we have improved upon their

technique and find that our results can be repeated by laboratory assistants having no previous knowledge of the method. Our modification consists in treating two phosphate solutions of a definite hydrogen ion concentration of $P_H = 7.3$ and 7.4 respectively with 1/10 of their volume of a 0.01 per cent solution of phenol sulphone-phthalein (the indicator used by the American workers). 5 c.c. of the broth are also treated with 0.5 c.c. of the indicator solution and are then titrated with standard acid or alkali (containing the correct proportion of indicator) until the colour of the broth is intermediate between that of the two standard solutions, since the broth itself is coloured this has to be compensated for by observing the standard tubes through a layer of broth. We have designed a special holder for the tubes which is shown in the figure. By the use of two standard tubes we find that we can adjust the reaction more exactly than by comparison with the single standard employed by Hurwitz, Meyer, and Ostenberg. Test-tubes of thin clear glass are used, having an external diameter of five-eighths of an inch. These can be obtained from Messrs. Baird and Tatlock, 14 Cross Street Hatton Garden, London, E.C. ("tubes for colorimetric comparison"). The tube holder is supplied by Mr. C. H. Nicholl, 1, Mackenzie-road, Cambridge.

The following solutions are required—

A. The indicator—0.1 gm. of phenol sulphone-phthalein (which may be obtained from Martindale, 10, New Cavendish Street, London, W.) is transferred to a litre measuring flask and treated with 10 c.c. of N/10 sodium hydroxide and about 500 c.c. of distilled water (previously boiled and cooled). 10 c.c. of N/10 hydrochloric acid are then added and the volume made up to 1 litre with distilled water.

B. Phosphate mixture $P_H = 7.3$ —Dissolve 9.035 gm. of pure disodium phosphate ($Na_2HPO_4 \cdot 2H_2O$) and 2.133 gm. of pure mono-potassium phosphate ($KH_2PO_4 \cdot 2H_2O$) in distilled water and make up the volume to 1000 c.c. with freshly boiled distilled water. To 100 c.c. of the phosphate solution add 10 c.c. of solution A, stopper, and keep in the dark.

C. Phosphate mixture $P_H = 7.4$ —Dissolve 9.596 gm. of disodium phosphate and 1.743 gm. of mono-potassium phosphate in distilled water and make up the volume to 1000 c.c. with freshly boiled distilled water. To 100 c.c. of the phosphate solution add 10 c.c. of solution A, stopper, and keep in the dark.

D. N/20 hydrochloric acid—To 1000 c.c. of N/10 HCl (or 100 c.c. N HCl) add 182 c.c. of solution A, and distilled water to make the volume up to 2000 c.c. Keep in the dark.

E. N/20 sodium hydroxide—To 1000 c.c. N/10 NaOH (or 100 c.c. of N NaOH) add 182 c.c. of solution A, and distilled water to make the volume up to 2000 c.c. Keep in the dark.

Six tubes are placed in the holes of the box and to them are added the following solutions—(2) and (6) Some of the broth

5 and 6. Box to hold test tubes for colorimetric estimation

(4) Distilled water. (1) Some of solution B. (5) Some of solution C. (3) 5 c.c. of the broth accurately measured and exactly 0.5 c.c. of solution A. (It is essential that the broth for this tube should be boiled for half a minute in a test tube and well cooled under the tap before it is measured, because subsequent sterilisation causes a change of P_H .) The box is then held up to the light and the tubes examined by looking through the slots X, Y, Z. It will then be noticed that Z is redder than X. It is necessary to adjust the reaction of the broth in 3 so that Y appears to be intermediate in colour between X and Z. If it is redder than Z, more must be titrated with the acid solution D. If it is yellower than X, it must be titrated with the alkaline solution E.

For the titration microburettes are employed containing 2 c.c. graduated in 150 c.c. so that they can be read to 1/100 c.c. The acid or alkali is slowly added to Tube 3 until its colour is judged to be intermediate between the two standard tubes when they are viewed through the box. Should

³ Bulletin of the Johns Hopkins Hospital, Baltimore, vol. xxvii, No. 293, p. 16 (January 1916).

the titration be performed with the acid solution, allowance has to be made for the change in reaction that occurs from the loss of CO_2 in the subsequent sterilisations. A rough method of overcoming this difficulty is to boil the contents of Tube 5 for 15 seconds, cool thoroughly and add more acid until the reaction is again correct. This may have to be repeated more than once. Normal hydrochloric and normal sodium hydroxide (and N 10 HCl and N 10 NaOH if the total amount required is expressed in more than two decimal places) is then added to the bulk of the broth, depending on whether acid or alkali was used for the original titration. For every 0.1 c.c. of N 20 acid or alkali required for the titration of 5 c.c., 1 c.c. of normal acid or alkali is added to each litre of the tryptic broth. If special accuracy is required the bulk of the media can be re-standardised after steaming sterilisation by steaming on three consecutive days is preferable to autoclaving. The medium is now ready for distribution and use.

We think we can substantiate the following claims for this broth —

1. It is *very much cheaper than peptone* and is at present about one-fifth the price of 2 per cent. peptone water, not costing more than 1.5d. per litre including the cost of the pancreatic extract, &c. used.

2. It is sufficiently *crystalline in composition* to yield uniform results.

3. The reaction is constant and can readily be brought to any desired hydrogen-ion concentration, though we suggest that the reaction we have chosen be adopted as a standard suitable for most purposes.

4. On it a *luxuriance of growth* can be obtained with a rapidity that we have not approached with any nutrient peptone. With the colon-typhoid group a very distinct growth can usually be seen in four hours.

paratyphosus A on glucose. Often in cases when no gas is produced on glucose peptone water the same organism grown in glucose-tryptic broth shows an appreciable amount in about 24 hours as is clear from the accompanying table. Tryptic broth diluted as above and 2 per cent. peptone water both containing 1 per cent. glucose and litmus as an indicator were the media compared, for gas production small Durham tubes of uniform diameter were employed and the amount of gas in them was measured in millimetres.

Among other sugars investigated were dulcitol, mannite, and levulose but the above results obtained with glucose are almost identical with those obtained with the other sugars except that dulcitol ferments the slowest.

It was found advisable to dilute the tryptic broth with an equal volume of sodium chloride, because at this dilution acid and gas are more readily produced than in a higher concentration. Our previous work on the final hydrogen ion concentration reached in glucose solutions leads us to believe that organisms in media containing an abundant supply of nutrient substances will not attack the carbohydrate contained as readily as they will in a medium which is deficient in these substances. A curious fact, however, has been noticed. In the undiluted digest ('stock broth') acid and gas are produced some time later than in the diluted tryptic broth, yet at the end of about 14 hours the amount of gas formed in the stock broth equals that in the dilute broth, and subsequently the gas in the undiluted broth increases out of all proportion to that in other dilutions.

7. The broth is an excellent medium for the preparation of agar, the requisite amount of agar being added to the tryptic broth prepared and standardised as above.

8. Its standard composition also renders it admirably suited to special media such as Endo &c.

Table showing Acid and Gas Production on Tryptic Broth and Standard Peptone Water

Organism	Broth	5 hours		7½ hours		10 hours		12 hours		24 hours		48 hours	
		Acid.	Gas.	Acid.	Gas.	Acid.	Gas.	Acid.	Gas.	Acid.	Gas.	Acid.	Gas.
B. paratyphosus A 16	— { Tryptic Standard	—	0	—	0	++	0	+++	0	—	3	20	Trace
B. paratyphosus A 17	— { Tryptic Standard	—	0	+	0	++	0	+++	0	—	1	20	0

— indicates no change of reaction.

++ indicates full acidity.

The figures indicate the amount of gas in the Durham tubes.

— indicates marked acidity.

measured in millimetres—e.g. — 0 = marked acidity no gas.

This luxuriance has not only been observed with the above group but also with B. diptherie and meningococcus (stock cultures). It is at present being tested with B. tuberculosis, gonococcus and other 'delicate' organisms. These results together with those on toxin production will be published shortly should they prove to be of any value.

5. It is of the utmost use for testing indol formation owing to its richness in free tryptophane, the precursor of indol. The indol reaction can be obtained in five hours with B. coli, and after 12 hours a culture of typical strains of such an organism smells strongly of indol. We can recommend the indol test devised by E. Nelson which depends on the orange colour produced by indol in the presence of vanillin and concentrated hydrochloric acid.

6. When diluted with its own volume of 0.5 per cent. sodium chloride it proves an excellent medium for the detection of acid and gas formation. At this dilution it is much superior to the ordinary standard medium (2 per cent. peptone water). It is true that the effect is not so marked with organisms that produce acid and gas readily but it is very evident with those that ferment slowly. For example we find that we have entirely overcome the difficulty so often experienced in obtaining gas from many strains of

9. There are indications that the restraining power of brilliant green on B. coli is especially selective in this broth, and we hope that the standard properties of the broth will make it possible to adjust it to any given sample of brilliant green once and for all, thus avoiding the necessity of re-standardising for each sample of peptone. This and other points are, however, still under investigation, but we hope to publish the results shortly.

LITERARY INTELLIGENCE.—Dr T. W. Eden and Dr C. Lockyer, obstetric physicians to Charing Cross Hospital, have just seen through the press a book entitled Gynaecology for Students and Practitioners. The illustrations to the number of 530 have been drawn in most cases from originals in the Lockyer collection in the museum of the Charing Cross Hospital Medical School. The volume will be published in July by Messrs J. and A. Churchill. An author's note entitled 'The Book of Sorrow,' compiled by Captain Andrew Macphail, of the Canadian Army Medical Corps, is announced for early publication by the Oxford University Press. In the preface written in warrant for completeing now a task begun in times of peace, and offering as a comfort to other hearts what volume will be uniform in style with the 'Oxford Book of English Verse.'

THE SHOCKLESS OPERATION

By P LOOKHART-MUMMERY, FRCS ENG,

SENIOR SURGEON TO ST MARK'S HOSPITAL, CITY ROAD E.C. AND TO THE
QUEEN'S HOSPITAL FOR CHILDREN HONORARY SURGEON TO KING
EDWARD VII'S HOSPITAL FOR OFFICERS AND SPECIAL
CONSULTING SURGEON TO THE CITY OF LONDON
AND FULHAM MILITARY HOSPITALS

SURGERY has at last succeeded in achieving the truly shockless operation, and it has become possible to perform a long and serious operation upon a patient with the certainty that shock will not complicate the procedure. This is a great advance in the history of surgery, one comparable to the achievement of the aseptic operation as the result of Lister's discoveries, although not so important as the latter, since shock is not so dreaded or so common a complication as was sepsis before the discovery of antiseptics. Like the discovery of antiseptics it is the direct result of the application of principles worked out in the scientific laboratory and subsequently applied in the operating theatre. It is a brilliant result of the application of experimental science to operative surgery—the only true method of progress. Like the discovery of antiseptics, it opens up all sorts of possibilities in the future and removes yet another of the barriers in the way of surgical enterprise. It has now become possible to perform a serious and prolonged operation—such, for instance, as complete excision of the rectum or the removal of a large tumour from the abdominal cavity—without any fear of producing shock and in fact without any disturbance to the patient's general condition, without even increasing the pulse rate. Further, it is now possible to perform serious operations upon quite elderly people and upon what the insurance companies call "bad risks" with a very considerable degree of confidence.

The ideal method of repairing the human body, were it possible to treat it as a machine, would be to remove the damaged part, such as an eye, a foot, or a hand repair it under the best and most advantageous conditions, and then reattach it to the body to which it belonged, in the same way as we should do in the case of a motor car or any other man-made machine. By such a process, repairing the part would not cause any injury or inconvenience to the human body to which it belonged beyond that incidental to the body's being deprived temporarily of the part to be repaired. Unfortunately, this method can never be possible in dealing with the human body, but the shockless operation is the same in principle. The damaged part is isolated from the rest of the human body by local and regional anaesthesia while it is being repaired and at the same time the patient is kept in a condition of artificial sleep, so that the body, through the brain and special senses will not be damaged from the psychological influences incidental to the operation which is necessary to repair the damaged part.

In a shockless operation the area of the operation is shut off from the sensorium by means of local anaesthesia. This anaesthesia must be so complete that if the patient were conscious no pain would be felt. Every sensitive tissue is injected with a solution of 1 in 500 novocaine before being divided, or what is better if it can be done the main sensory nerve trunks are injected so as similarly to shut off the desired area.

The operation itself is performed in such a manner as to cause the least possible trauma—that is to say with light handling and sharp cutting tearing and blunt dissection being inadmissible. Meanwhile the patient is kept in a condition of artificial sleep by a suitable combination of anaesthetics. First of all a preliminary injection of morphia (or morphine and scopolamine) is given the dose of which varies according to the type of patient and is roughly from 1/8 to 1/3 gr. This should be given an hour before operation, so that the full effects are felt at the time of induction of anaesthesia. Secondly, a general anaesthetic is administered in order to keep the patient quite unconscious. The object of the general anaesthetic however is only to produce unconsciousness and not relaxation or even anaesthesia. The method of combining several forms of anaesthesia was first suggested by Dr G. W. Crile who called it 'anoci-association' anaesthesia because its object was to cut off from the patient's central nervous system all nociceptive (or harmful) impressions. This name while it may have advantages

from a purely scientific point of view, is rather clumsy and has little to recommend it. Nor does there seem any necessity to label this method with a name. It is simply an improved technique by which the shockless operation can be attained.

The best general anaesthetic, in my opinion, is gas and oxygen, ether or chloroform being added if necessary, but only used in very small quantities and for a few minutes at a time, as, for instance to help during the induction of anaesthesia in a very muscular or alcoholic subject, or to tide over a period during which it is necessary to handle some part of the abdominal contents which cannot be properly isolated by local anaesthesia. The form of gas and oxygen anaesthesia which appears to me to give the best results is by re-breathing into a large bag, oxygen and fresh N₂O gas being added as occasion demands. This is the method used by Mr J. H. Chaldecott who has given the anaesthetic for most of my cases, and the one with which I have certainly obtained the best results. The total amount of gas used is very small, in one case only three-quarters of a 100 gallon cylinder of nitrous oxide gas was used in 1 hour and 50 minutes. The patient is kept under the anaesthetic until he is back in bed, and in most cases is conscious in three or four minutes after the mask is removed.

The important point about the general anaesthetic is that instead of the gas or drug being used, as hitherto, to produce anaesthesia, it is only given in sufficient quantity to produce unconsciousness, sometimes hardly that. The ideal condition is the one in which the patient will react to stimuli will answer if spoken to loudly, or move if hurt. I always ask the anaesthetist to let me know if he sees any sign of stimulation, as this is evidence that the local and regional anaesthesia is not efficient.

Many factors have to be considered before successful results can be obtained. Not the least important is the technique of the surgeon. Those surgeons who tear and separate the tissues with their fingers and who perform most of the operation by what is called 'blunt dissection' can never hope to attain to the really shockless operation. There are some surgeons whose only use for a knife is to cut through the skin, and who perform most of the operation with their hands assisted by blunt instruments. They point often with pride, to the speed with which they can work and to the small amount of bleeding—advantages, it is true, but obtained at a heavy cost in other respects.

The shockless method of operating involves a somewhat more elaborate technique, and, at first at any rate, takes longer than if a general anaesthetic alone is used. With increased experience in the method the only extra time added on to the operation is that taken up in injecting the local anaesthetic, and should not amount to more than five or ten minutes in a long operation. On the other hand, the shockless method of performing an operation makes the length of time occupied in performing an operation of much less importance since the amount of general anaesthetic used is relatively much less and shock cannot occur. So far I have seen no harmful results from the injection of novocaine, even though I have often in a big operation used as much as 4 or 5 ounces of a 1-500 solution. No difference can be seen in the tissues at the end of the operation and the healing of the wound is in no way altered or delayed. The only contra-indications to the method that there would seem to be are in some septic cases where there might be danger of spreading the infection by the injections and in some cases of cancer where there might be a similar danger of spreading cancer cells. The latter should seldom occur as no operation for the removal of cancer should ever involve cutting through tissues infected with cancer cells. In any case these objections do not apply if the nerve trunks are anaesthetised by regional anaesthesia.

The use of urea quinine hydrochloride has certain disadvantages. It may cause an oedema lasting several days though I believe this is due to the use of too large and too concentrated solutions. Personally I do not like to inject it into the immediate neighbourhood of the wound.

The advantages of the shockless method of operation are much lighter anaesthesia with consequently less probability of subsequent sickness, almost complete absence of operative pain, absence of rigidity and most important of all complete absence of shock even after very long and prolonged operations.

J. H. Chaldecott and C. W. G. Bryan, The Value of Anoci-Association Tbx LANCET, Ser. C, 1915, p. 721

The great advantages are more particularly seen in serious operations upon elderly or feeble subjects and where an operation has to be performed upon an individual who is especially liable to have post-operative vomiting. In any case, the advantages from the patient's point of view are not inconsiderable, and seem to me to be well worth the additional trouble involved in the operative technique. The absence of post-operative vomiting is a very great advantage, as it is impossible to estimate the amount of damage which may often result in abdominal cases from the straining which necessarily accompanies vomiting. Surgeons have become so used to post-anæsthetic vomiting as a necessary evil after operations that they do not worry about it, but they will all agree that it is a most undesirable complication after an abdominal operation. It tends to start hæmorrhage afresh, it makes the stitches cut into the skin, it causes severe pain in the wound, it prevents sleep, it stops digestion, and, in fact, it would be hard to find any other complication which could cause as much damage to the surgeon's handwork as vomiting. Complete rest for the abdominal cavity is what every surgeon desires for some hours after he has performed a laparotomy but this is exactly the opposite of what occurs if there is vomiting. Allowing the patient to walk about immediately after an abdominal section would be considered little less than criminal and yet it could not possibly do as much damage as vomiting.

The following cases are quoted as showing the advantages of this method in special cases.

CASE 1.—A fragile woman, aged 71, was sent to me by her medical attendant on account of a large tumour in the left side of the abdomen which was causing her acute pain. This pain was not relieved effectually by drugs, and she was very anxious to have something done. The tumour which proved to be a chronic tubercular kidney, occupied the whole of the left side of the abdomen and after removal was found to weigh nearly 7 lb. The operation was performed by the shockless method 15 gr. of morphia being given before the operation and continuous gas and oxygen used with local and regional anaesthesia. The operation of removing the kidney occupied 50 minutes for as it was very much fixed by adhesions its removal was quite a difficult matter. Three minutes after cessation of the anaesthetic the patient was quite conscious. She was not sick at all, she had no after pain and she was able to have her ordinary tea at 4.30 in the afternoon. Her pulse-rate never altered at all as the result of the operation and she appeared to suffer no inconvenience in consequence of the operation.

CASE 2.—I first saw the patient a woman aged 75 with her family physician on account of a large carcinomatous growth situated at the junction of the rectum and sigmoid. She was exceedingly anxious to have this removed if there was any chance of a successful result. A preliminary colotomy was performed and ten days later the operation was carried out in the same way as in the previous case. The entire rectum and surrounding skin were removed together with some inches of the sigmoid flexure. The peritoneal cavity was extensively opened up, and 3 inches of bowel were removed. The operation took 1 hour 50 minutes. The patient was conscious in less than five minutes after being back in bed and her pulse-rate was only 8. She never caused the slightest anxiety or showed any signs of distress as the result of the operation. She was not sick and did not lose her appetite. She was able to return home in less than a month after the operation.

CASE 3.—A hospital patient aged 62, was admitted to St. Mark's Hospital with a large growth at the upper end of the rectum involving the posterior vaginal wall. She was a very fat and plump subject and appeared to be a very unsuitable individual for a serious operation. She was operated upon by the same method the operation taking nearly two hours. She left the operating table with a pulse of 50, was not sick, showed no signs of shock and caused no anxiety. She was out of bed three weeks after the operation.

CASE 4.—An army officer aged 52 was sent back to England from a military hospital suffering from carcinoma of the upper part of the rectum and having just recovered from a serious attack of dysentery. He appeared to be in the condition in which he had risked an operation. The operation was performed by the shockless method and took about two hours. The pulse-rate was not at all increased, the patient was conscious a few minutes after the operation and two hours later was propped up in bed reading the news paper. I was difficult in fact to believe that he had undergone a serious operation.

CASE 5.—The patient a woman aged 73, was operated upon for a chronic intestinal obstruction. The operation took 1 hour 10 minutes and was performed under gas and morphia. She was not sick. A thorough search of the abdominal cavity was necessary to find the obstruction which proved

to be a band of adhesions (there was considerable distension of all the intestines). The uterus and bladder were stitched up to the anterior abdominal wall to rectify a prolapse. The pulse-rate never went over 84. The patient was not sick, and she recovered without causing a moment's anxiety.

It is my belief that these patients could not have been operated upon successfully in the ordinary way, or at any rate that the risk would have been so great that one would have hesitated to attempt the operation. By the shockless method, however, they were not only able to get through the operation satisfactorily, but they never caused the slightest anxiety and there was nothing in their general condition a few hours after the operation to indicate that they had undergone an operation. All of them were not only hungry but able to digest their food within 24 hours of the operation.

It must not be supposed that the shockless operation is just a new method which can easily be adopted. It is not so much a method as a series of principles by the careful co-ordination and co-operation of which the desired result can alone be obtained. The surgeon who wishes to achieve success with the shockless operation must have much patience and take a great deal of trouble to acquire the necessary technique, and he must have an anaesthetist, an assistant, and nurses who understand and are capable of applying the necessary principles.

The credit for the discovery of the shockless operation is due almost entirely to Dr. Crile. Although for more than 12 years I have been working in the same experimental and clinical field I have not had his opportunities, as in this country every difficulty is placed in the way of experimental work instead of its being encouraged as it is in America. In my Hunterian lecture on the Physiology and Treatment of Surgical Shock, published in 1905 I predicted the coming of the truly shockless operation and Dr. Crile's investigations have now rendered this an actual fact. From 1905 to about 1908 Mr. W. L. Symes and I carried out a number of experiments at the University of London the object of which was to ascertain what were the important factors in abdominal operations tending to produce shock and how they might best be combated or avoided. Briefly, we proved that there was a great difference in the shock-producing effects of different kinds of wounds. Whereas wounds made with sharp instruments and accompanied by gentle manipulation, even if extensive produced very little shock, the exact reverse was found to be the case with wounds produced by blunt dissection and accompanied by rough handling of the tissues. Further, we found that preliminary injection of morphia tended markedly to prevent shock. Our conclusions were never published. Fortunately similar but much better and more exhaustive experiments on the same lines have been performed by Dr. Crile in America, and his results have been published. It is satisfactory to note that his conclusions are the same as those at which we have arrived, although he has carried his proofs much further than we were able to do. Another result of our experiments was the discovery of the value of extract of the infundibular portion of the pituitary gland in combating shock. Since then this extract has been to some extent standardised, and is one of the most valuable drugs we possess for its effect upon the unstriated muscle-fibre.

My chief excuse for this paper is that the shockless operation does not seem to have received the attention from English surgeons that it deserves. Very few surgeons in this country appear to be using the method at present. Sir Berkeley Moynihan advocates it as a routine method, but still apparently reserves it as the main general anaesthetic. Colonel H. M. W. Gray has also adopted this method, and has advocated it in a recent paper. The present war has interfered very seriously with all advances in surgery which have not a direct bearing upon the treatment of the wounded, and a somewhat elaborate technique, such as is here involved, is doubtless very difficult of application on the field. This is to be regretted as the condition of seriously wounded men requiring immediate operation is one particularly predisposing to shock.

INTESTINAL TOXINS AND THE CIRCULATION

By D T BARRY, F.R.S. ENG., M.D. RUI
PROFESSOR OF PHYSIOLOGY, QUEEN'S COLLEGE, CORK

FOLLOWING up the investigation of the action of excretory toxins on the neuro-muscular mechanism of the heart, I have tried to ascertain approximately the level at which the alimentary toxin begins to be formed

As in the previous experiments, the toad's heart was perfused through the inferior vena cava, using the intestinal contents, which were mixed with Ringer's solution in a mortar, and the solution rapidly filtered with the aid of a water pump. Too much filtration with long exposure to the air diminishes rapidly the toxicity of the extract. Dogs and cats which were used for class demonstrations provided the material. An attempt was made to remove the toxin by dialysis in a collodion dialyser as recommended by Bigelow,¹ but the dialysate was almost inactive. Most of the cats received in this laboratory suffer from nematode worms, and in these cases, if we get over the difficulty of finding a sufficient quantity of material—the small intestine is almost empty—the toxic effect is slight. The worms, *plus* the contents got by gentle scraping of the gut in these cases, were pounded in a mortar with Ringer's solution.

The effects on the blood pressure and heart beat of intra venous injection of the intestinal contents of the animals themselves were also investigated. A glass tube was tied into the external jugular vein and about 5 c.c. of the extract allowed to run into the circulation, after previous warming to a temperature of 37° C. Prolonged warming even at low temperatures, diminishes the toxic action.

It is well known that the mucous membrane of the intestine contains depressor substances, extracts made in the preparation of secretin, for instance, showing their presence. Light superficial scraping, however, does not extract them. In the present experiments where the contents were abundant no scraping was necessary, but it was employed very lightly when the contents were sparsely found. Injections of light scrapings have been practised in the investigation of hormones affecting the secretion of intestinal juice, but without marked blood pressure changes.

Method

The method employed was to subdivide the small intestine into upper middle, and lower thirds, of which the contents were mixed with Ringer's solution 5 gm. in 50 c.c., filtered and neutralised. In the text these extracts are numbered 1, 2, and 3 respectively from above down. The contents of the caecum were also used and this mixture is numbered 4. In each case the animal is specified "2 cat," for instance meaning the contents of the middle third of the cat's intestine.

All the extracts were acid to phenolphthalein and were made neutral by the addition of standard alkali and certain indicators. With these indicators it was estimated, according to the table given by Bayliss,² that the H concentration was between 1×10^{-7} and 1×10^{-8} in all extracts used. With phenolphthalein the hydrogen ion concentration is 1×10^{-8} when the colourless solution just changes to pink. A definite pink colour was allowed to develop in the extracts with this indicator by dropping in the alkali and this was then just dispersed by careful addition of further extract. The solution then gives a faint orange tint with neutral red, and pure red with Congo red.

The glass cannula used in the former experiments was discarded in the present series for a junctional piece consisting of vulcanite. This is of crucial form the bore being one millimetre throughout. It was made for me by Messrs. Hawksley and Sons. One limb of the junctional piece is attached by rubber tubing to a small glass cannula of which the bore does not exceed one millimetre. The other three limbs are connected with perfusion bottles. This arrangement facilitates washing out and changing of the fluid in one or more bottles without removing the cannula from the vein. The dead space in the combination is almost negligible. The rate of flow was regulated in the manner

described in a previous paper.³ One perfusion bottle always contains Ringer's solution and the other two the material to be examined for toxic effects. The aorta were cut across to give free exit to the fluid. All the records read from left to right. Tracings of the auricle (upper) and ventricle (lower) are given. Most of the extracts show a toxic action on the muscle or nerves an effect which is slight in the upper portions of the gut and increases as we proceed downwards. Speaking generally, the varying effects can be interpreted in terms of degree or intensity of action. The most marked action is on the ventricle or on the auriculo-ventricular bundle.

A simple and uniform loss of power in the contractions without change of rhythm (Fig. 1) is sometimes seen but it

FIG 1

Record of auricular (A) and ventricular (V) contractions of a toad's heart perfused with extract (1) of cat's intestine for the period between the crosses. At the thick line the drum was stopped and Ringer's solution perfused. The record reads from left to right.

is not usual, irregularity of the ventricular beat being one of the most common and prominent features. In the first tracing, 1 (cat), it will be seen that the ventricle fades off in force some time before the auricle is affected and the rhythm is maintained. At the thick line the drum was stopped for a few minutes, during which perfusion with Ringer's solution was carried out. This fully restored the beat, but the rate on recovery was somewhat slower than previously. The accelerator fibres to the heart undergo depression in these cases, as is shown by a stimulus applied to the crescent which before perfusion gives initial acceleration, but subsequently to perfusion gives none. There is no increased tone, rather the reverse, and the action has to be described as an enfeebling one, especially on the ventricle with no appearance of block. Further perfusion with the same extract gave similar results. A general consistency of action has been noticed for a particular extract allowing for the fact that the toxicity tends to disappear with time.

A more common result from No. 1 toxin is a change of rhythm (Fig. 2). In the first part of this tracing, 1 (dog)

FIG 2

Toad's heart perfused with extract (1) of dog's intestine. At the point marked with a cross the 2:1 rhythm was stopped and extract 2 (dog) substituted. At C the heart block follows.

only every other beat of the auricles succeeded in setting over an effective stimulus to the ventricle—this is a 2 to 1 rhythm. At the point marked with a cross the drum was stopped for about half a minute during which per-

¹ Bigelow and Gemberling Jour Amer Chem Soc 1907 p 1476.
² Principles of General Physiology 1915 p 129

with No 2 from the same source (dog) was carried out. The effect of this is seen in complete block of four auricular stimuli. The last few beats of the ventricle before the drum resumed its movement were very feeble. On recovery the previous 2 to 1 rhythm is shown. This is a true example of block and must be due to lowered conductivity of the a-v muscle.

No 3 extract from this source first caused change of normal rhythm to 2 to 1. On continued perfusion for a few minutes it caused tone changes and tremor of the ventricle with slowing of the auricle (ventricle rate). It is only after somewhat prolonged action that the auricular muscle (or nerves) shows any marked effects. Perfusion with Ringer's solution for about one minute (drum stopped) gradually restored the beat, but for some time it remained at 2 to 1.

The effects of No 4 (dog) mixture were somewhat more pronounced. (Fig 3) There is marked increase of tone in the auricles, slight increase in ventricle tone at first, and subsequently block. The arrest is purely ventricular, the auricular contractions, though small in the record, being distinct. The perfusion was stopped when the ventricle was arrested. The quiescent ventricle, of course, tended to keep

FIG 3

Total heart perfused with extract (4) of dogs intestine. Perfusion was stopped when the ventricle was arrested.

the auricular pressure up but the increased tone is mostly independent of mechanical pressure effects, although it is relaxed by the relief of pressure with the first few beats restored in the ventricle. Slight changes in perfusion pressure, even if they occurred, could not of themselves cause these effects.

No 4 (cat), a weak solution, gave in one case increased auricular tone with irregularity which in the ventricle partakes of the character of extra systoles without compensatory pause. There is no block. An increase in calcium ions in the perfusing fluid would cause increased tone changes in the muscle. Calcium, mostly in insoluble form is excreted by the large intestine. It cannot affect the results to any appreciable extent.

Where the ventricle is arrested as described its irritability and contractility are lost only for a brief period. Except in the early phase of quiescence it responds by contraction to an electrical stimulus. This contraction is single, or the stimulus if applied late in the quiescent phase may cause a regular sequence of beats thus anticipating by a few seconds the spontaneous resumption of the rhythmic contractions. More time is necessary for the recovery of conductivity than for the other properties. The oneness of these properties as maintained by Hering, Muskens, &c. is difficult to credit. Engelmann's view of their independence of one another because ministered to by independent nerve units (bathmo-chrono- and dromotropic filaments) fits in more accurately with common observation, especially of the action of toxic substances.

Intravenous injection.—The animals employed for testing the effects of injection into the circulation were used subsequently for ordinary demonstrations. Complete anaesthesia had to be induced, and a fast of some 12 hours or more

preceded the operations, consequently the amount of material to hand in the upper portions of the gut was small, yielding no more than 5 c.c. of a 10 per cent extract. This was the quantity used throughout.

The records given are from the dog. The blood pressure was recorded by a mercury manometer, either alone (Fig 4) or in conjunction with a Hürthle tambour (Fig 5). The advantage of using a Hürthle or some form of sphygmoscope is that it facilitates counting the heart beats, the mercury manometer being unreliable for this. The upper tracing is that of the mercury manometer. A cannula was inserted into the left common carotid artery and made to communicate through a Y shaped piece with the manometer and

FIG 4

Blood pressure record of a dog taken with a mercury manometer. At the mark on the horizontal line an intravenous injection of its own extract (2) was given.

Hürthle tambour. The pressure was first raised in these after expelling air to about 150 mm Hg. The breathing is recorded by tambours in Fig 5. It will be seen that the principal change is a fall in blood pressure, which is slight from the material of the upper and middle reaches of the gut (Fig 4). The drop in B.P. in this latter case was given by No 2. The point of injection is marked on the horizontal line, the time record gives seconds. There is very little change in the rate and force of the heart beat. Fig 5 shows the effect of No 3 extract injected into the vein, the vagi being cut. With intact vagi there is a fall of pressure soon after the injection at the end of which there is some increase of heart rate and gradual recovery. With vagi cut (Fig 5) there is also a fall of pressure which is, however, more rapidly recovered from. In this record irregularity of the heart-beat is pretty well shown, and this factor apparently plays a part in the pressure change.

FIG 5

Blood pressure record of vagotomized dog with mercury (M) and Hürthle (H) manometer. The respiration (R) is also recorded. At the mark extract (3) was injected intravenously.

There seems little doubt that substances having a deleterious action on the heart musculature and nerves are formed both in the small and large intestine, even under apparently normal circumstances. It is quite conceivable that such products whether of bacterial or ferment action, may on occasion exist in excessive quantity and find access by absorption to the circulation, or that certain conditions might determine undue absorption when they exist in ordinary amounts. It is well known that certain products—indol, skatol, &c.—in themselves toxic, are made harmless by oxidation, absorbed and excreted as sulphates. I have remarked in the experiments that undue exposure overmuch filtering or delay tends to diminish the action of the intestinal toxins, thus suggesting their volatile nature.

Peptone has a depressing effect on the blood pressure but practically no peptone is shown to exist in those regions of

* Arch. d. ges. Phys. Band lxxxvi. p. 533.

* Amer. Jour. of Phys. vol. I. 1938.

* Arch. f. Phys. 1900 p. 315.

the gut where the toxicity is most marked. If we acidify and boil the contents of the lower end of the ileum, filter, and add alcohol or tannic acid to the filtrate, it gives no appreciable precipitate.

The results of perfusion of the toad's heart give us a much more reliable indication than those of intravenous injection in the mammal. In the latter the quantity injected is small and the time of action short. It is reasonable to assume that prolonged absorption even in minute quantities would produce effects on the mammalian heart similar to those immediately produced in the toad's heart by comparatively strong concentration. The excised mammalian heart may prove suitable for perfusion with more concentrated solutions, but the difficulties of technique would not be light.

Many conditions of irregularity and block observed in the human heart in Stokes-Adams and other affections seem to fall into line with the action of these substances. Osler¹ says that poisons arising in the intestine may cause arrhythmia. Flatulence, he says, may cause it reflexly. A neurotic group of cases is described where no post-mortem lesions are found. In the matter of treatment the same author makes brief reference to dieting and the importance of avoiding full meals and flatulency.

A systematic course of treatment of the alimentary canal antiseptically and otherwise should be of the greatest service in some of these cases. Theoretically there are substantial grounds for the adoption of such a course, the arranging of the practical details of which is, however, in the province of the observant practitioner.

Cork

KALA-AZAR IN SOLDIERS RETURNING FROM MALTA

By GORDON R WARD, M D LOND,
CAPTAIN R.A.M.C. (S.R.)

THIS preliminary note is based on two cases which have come under my notice during the last 12 months, and is written with the hope of drawing early attention to the following facts—

1 That cases of kala azar are to be expected among men returning from Malta and who have never been farther East than that point.

2 That the diagnosis is likely to be very difficult to those unacquainted with tropical diseases.

3 That the prognosis must not necessarily be regarded as hopeless.

These facts may be well known to those who have had the opportunity of studying tropical medicine, but they deal with a field of study necessarily almost unknown to the average general practitioner, yet it is the general practitioner who is now treating the majority of the returned troops, and there can be little doubt that he will have to practise, after the war, amongst diseases which have hitherto been merely names to him. It is hoped that the writer's experience may be of some assistance to others.

Owing to certain anomalies in the first case and to the fact that the second case is now under treatment no attempt can be made at present to give a full description. The diagnosis and treatment are of first importance, but these must be prefaced by a few more general remarks.

Kala azar (the "black fever") is well known in India and until the causal parasite—the *Leishmania donovani*—was discovered by the R.A.M.C. officers whose name it bears was commonly supposed to be a manifestation of malaria. This fate of course has been that of most varieties of splenomegaly in the tropics and even at one time at home. Beyond India it has been recognised particularly in the Mediterranean, but here it was chiefly met with in children and this peculiarity has led some people to suppose that the Mediterranean form is a different disease. However this may be the course of the disease when it attacks adults seems to be the same as that of the Indian form.

The first symptom is either referable to general enfeeblement or to the splenomegaly and may be weakness, dyspnoea, indigestion and dragging pain. Diarrhoea is a common symptom and well marked pyrexia is characteristic. The wasting increases the skin becomes pigmented the splenomegaly assumes greater prominence and the patient dies

from exhaustion or from some intercurrent infective process. The duration of the disease may be anything from a few months to some years.

The diagnostic problem is somewhat as follows. A patient presents himself with diarrhoea continuing weakness, or some similar sign which would fit many disease processes. If a thorough examination is made and symptomatic treatment adopted there will be at the best brief subjective improvement. Eventually examination must be made and will disclose a large—probably a very large—spleen. This will naturally elicit a question as to whether the patient has been abroad and, this being answered in the affirmative, the diagnosis of some tropical disease is suggested. This is the stage at which my first patient arrived. He was sent for examination by his commanding officer with the remark that "he had not seemed fit for duty for two or three months, he had refused to report sick." He was noted to be very anæmic and was admitted to hospital, where the splenomegaly was quickly discovered. The medical officer in charge, who held the Diploma in Tropical Medicine, brought it to my notice with the remark that it was a case of leukaemia. On examination marked general pigmentation was noted. This is against a diagnosis of leukaemia, in which general pigmentation is quite uncommon. A blood examination was made forthwith and revealed a very low leucocyte count. This excluded leukaemia and suggested kala azar. It did not, however, rule out splenic anæmia. A spleen puncture, however, afforded abundant evidence of the nature of the disease, very many typical parasites being seen.

It is obvious that the conveniences of blood examination and spleen puncture may not always be available, and it is therefore pertinent to inquire how far a definite diagnosis can be arrived at without them. Absolute diagnosis is not possible unless the parasite be found, but the following points in a case of massive splenomegaly are most in favour of kala azar—viz., residence abroad, general pigmentation, absence of enlarged glands, deafness and falling sight (all of which may be found in leukaemia) and the temperature. The latter is peculiar in showing two daily rises, and a four hourly chart is necessary to show this. The first maximum is reached about noon, the second in the evening.

My second case was admitted to hospital after three or four months of increasing debility. He complained mostly of diarrhoea. When only a few days temperature readings were available they closely resembled a somewhat typical enteric defervescence. The diarrhoea and splenomegaly were held to be consistent with such a diagnosis although the extent of the latter was felt to be unusual and disquieting. Major A. Elliot of the 1st London Field Ambulance has kindly given me details of another case (also contracted in Malta) in which the same diagnosis was arrived at. It is therefore very important to remember that the splenomegaly of enteric is not nearly so marked as in kala azar and is not solid to the feel. A hard, massive spleen extending to the umbilicus or to the pubis can never be ascribed to typhoid, nor indeed is it likely to be associated with anything like so acute a process as any of the enteric group. In the second case spleen puncture was performed to place the diagnosis beyond doubt although reasonably definite parasites were found in the circulating blood.

One other point may be mentioned in diagnosis. The idea that kala azar was malarial amongst other factors gave rise to a very firmly rooted conviction that malaria could produce extreme chronic splenomegaly. Whether this is now held to be the case the writer does not know, but it is significant that Castellani and Chalmers in their "Manual of Tropical Medicine" give marked enlargement of the spleen as a diagnostic point in favour of kala azar as against malaria. No other authority is immediately available for reference.

As regards prognosis the same writers are likewise pessimistic stating that 70 per cent die with vigorous quinine treatment and 83 per cent without this. The first case mentioned recovered after taking from 60 to 70 grains of quinine daily by the mouth for three months. He has been on full duty for five months since. The second case is now taking 60 grains daily (reached by increments of 6 to 9 grains a day) and there is some slight diminution of the splenomegaly but his general condition is not improved. He has not been long under observation. Major F. H. informs me that the case he saw did not have any late doses of quinine and died eventually of carcinoma of the liver.

obvious that quinine ought to be pushed as much as possible in neither of my cases did large doses give rise to manifestations of quinine poisoning sufficient to annoy the patient, but when this is the case bromides are said to mitigate the symptoms

More recently Sir Leonard Rogers and others have used intravenous injections of 2 per cent tartar emetic in saline, and claim to have better results than by the older methods. The details of technique can be found in sundry papers published in the medical journals during the last year or two.

In conclusion, it may be stated that this note will have achieved its object if the general practitioner, to whom it is addressed, will think of the possibility of kala azar in the presence of splenomegaly in a soldier returned from abroad. There can be no doubt that the greatest difficulty in diagnosis is the realisation of what the disease may possibly be. Once kala azar is considered as a possibility the diagnosis presents no particular difficulty.

Sevenoaks, Kent

ABDOMINO-PERINEAL RESECTION OF RECTUM BY COFFEY'S MODIFICATION OF THE TWO-STAGE OPERATION

By LAURENCE C PANTING, M.D., B.Ch. Oxon,
M.R.C.P. Lond., F.R.C.S. Eng.,

SURGEON TO THE ROYAL CORNWALL INFIRMARY, TRURO

THE radical operation for cancer of the rectum as elaborated by Ernest Miles¹ must necessarily be a most serious surgical procedure for even in his very skilled hands it takes from an hour and a half to two hours to perform and the mortality reaches 22 per cent, other surgeons admitting a much higher figure. Apart from the grave injury necessarily inflicted on the tissues the mere duration of anaesthesia for such a prolonged period is serious and this danger is enhanced by the change in position of the patient required for the performance of the perineal portion of the operation. It is not surprising, therefore, that various plans have been suggested for dividing the operation so that it may be performed in two stages, the abdominal portion constituting the first and the perineal the second stage.

W. Mayo² expresses the opinion that by operating in two stages the mortality may be reduced to one-half of that occurring when it is performed in one. He suggests two plans for the division: the first to perform a colostomy without division of the bowel followed by Kraskes' sacral operation or some modification of it. This has the advantage that it can be employed in cases of obstruction and allows of cleansing the lower and diseased segment but beyond the fact that it permits exploration for metastases it has none of the advantages of the accepted abdomino-perineal operation but is really a modification of Kraskes' operation. The second method of which several modifications may here be considered is that usually adopted. It consists of a first stage at which the pelvic colon is divided and the ends closed, the lower end of the upper segment being brought through the abdominal wall as a permanent colostomy, while the lower segment is freed from its attachments and left to be removed by a perineal operation as a second stage.

In the treatment of the separated lower segment with its attached mesentery and glands several plans have been proposed. Mayo leaving the lateral attachments of the rectum in the pelvis intact in order to preserve the middle hæmorrhoidal arteries pushes the whole mass into the lower part of the pelvis and closes the peritoneum over it leaving it thus until it is removed in the second stage (perineal) operation six or seven days later. In one case of Mayo's and in several elsewhere recorded the blood supply has proved insufficient and perforation of the bowel has led to a fatal result. Another method which he has tried is to divide the bowel with the cautery between clamps the lower clamp being left in the wound surrounded by a thin rubber tube packed with gauze. Alternatively the bowel may be divided between ligatures³ the end inverted with a purse-string suture and the peritoneum sewn over it

to protect the peritoneal cavity. The danger of sepsis in thus dividing the gut low down in the pelvis in the presence of a sloughing growth is obvious and seems to constitute a very serious disadvantage to the plan. As a further alternative it has been suggested by Coffey⁴ that the lower segment should be inverted through the anus, which prevents any danger of sepsis to the peritoneal cavity since the bowel is not opened. The peritoneal surfaces which are in contact rapidly close the upper end so that when necrosis from loss of blood supply occurs, there is no longer any avenue open to the pelvic cavity. With these advantages it has, of course, certain limitations, thus, in the case of a large mass of growth it may be technically impossible to perform the inversion and get it through the anus. Another difficulty occurs where the growth actually involves the region of the anterior reflexion of the peritoneum from the rectum, but this, if sufficiently extended, must render any two-stage operation upon these lines nugatory and that to a greater extent in the other modifications than in this.

As some plan of invagination had for some time seemed to me more hopeful than anything previously described I at once adopted Coffey's method in the following case which came under my care, and it proved entirely satisfactory.

Mrs —, aged 49 years, was sent to me in October, 1915, with a view to operation for cancer of the rectum. She had been suffering for two years from symptoms due chiefly to a polypus which came down every time the bowels acted and bled fairly freely until it was replaced in the rectum. There was also an offensive discharge, but no obstruction and no pain which did not seem easily accounted for by the polypus. She had not appreciably lost flesh, and when seen she was well nourished and not more out of health than might be expected from the constant irritation and discharge. On examination a polypus of about the size of a plum was found attached by a thin pedicle to the anterior wall of the rectum just inside the anus. Some two inches above the anus a soft granular growth was felt, apparently encircling the bowel and reaching upwards as far as the finger could reach. The lower part was but little raised, while the upper part protruded into the lumen of the bowel. Nowhere could any fixation of the rectum be made out, the vagina was normal and the uterus freely movable. The liver was not enlarged, and nowhere could any glandular or metastatic deposit be felt.

As the case seemed suitable for operation the patient went to a nursing home, and on the night of her arrival the polypus came down and the opportunity was taken to remove it so that the rectum could be better cleared. The first operation was performed two days later. An incision was made from the umbilicus to the pubes in the middle line, and a preliminary examination made which showed the absence of recognisable metastasis. The pelvic colon was drawn out of the wound and a point selected in its lower part so that as much as possible might remain to form a reservoir for faeces. At this point the bowel was crushed and divided with the cautery between ligatures, the divided end being turned in and closed with a purse string suture. The mesentery was then divided back to the promontory of the sacrum and the superior hæmorrhoidal artery ligatured. The peritoneum was divided on either side of the rectum down to the base of the broad ligament and the whole mass of rectum with the soft tissues and glands separated from the sacrum as far as the upper end of the coccyx. The anterior reflexion of peritoneum from the rectum was divided, and finally the lateral attachments of the rectum. The portion of gut below the section with its adherent cellular tissue and glands had thus been entirely freed down to a point a little below the anterior reflexion of the peritoneum. A large rubber tube had been prepared shaped, and stitched so as to form a blunt point at one end and open at the other, and to act as a pilot for this a corresponding glass tube closed and rounded at one end. This tube with its pilot in position was now passed by an assistant through the anus and up the rectum, the end of the tube being guided by the operator's hand in the pelvis. When it was well in the rectum the glass tube was withdrawn and the rubber tube pushed on until it reached the closed end of the bowel. Here it was firmly fixed by stitches passing right through the gut and rubber from side to side. The tube was then slowly withdrawn, invaginating the upper end of the bowel into itself the walls being meanwhile supported by forceps on each side. This was continued until the whole of the free portion had been invaginated. The cut edges of the peritoneum in the pelvis were drawn together with stitches and in order to form a second peritoneal layer the uterus was drawn back and stitched to the peritoneum over the sacrum and laterally the peritoneal floor being thus firmly closed. The lower end of the upper segment was then

⁴ R. Coffey: Annals of Surgery, April, 1915.

passed through the left rectus by means of a separate incision and fixed to form a permanent colostomy, and finally the main wound sewn up.

The operation lasted one and a half hours, but the patient bore it extremely well, the pulse not exceeding 100. Next day, however, there was a good deal of discomfort from distension, which necessitated the opening of the colostomy in 48 hours after the operation. After this her recovery was rapid, there was no trouble from the necrosed bowel, which separated off on the sixth day, the temperature did not exceed 100° F., and in 14 days she appeared quite fit for the second operation, the wound being quite healed and the colostomy acting well.

At the second operation, with the patient in the extreme lithotomy position, a lozenge shaped incision was made round the anus and carried backwards to the sacrum. The coccyx was removed, the sacro-rectal space opened, and the dissection carried upwards until the closed upper end of the rectum was reached. Unfortunately the peritoneal adhesions at the invagination gave way during this manipulation, and septic material from the interior of the rectum escaped into the wound. This was sponged away and the opening closed as well as possible with a gauze pad while the lateral and anterior connexions of the rectum were separated. This was accomplished without much difficulty and the rectum and anus removed. There was some oozing from the deep part of the wound which caused delay. When this had been stopped the edges were sewn together and a large tube left in the sacral end of the wound.

There was a good deal of shock from this operation which lasted one hour, the pulse rising to 132, due in part, no doubt, to the oozing above mentioned, but chiefly, it seemed, to the anæsthetic, which on this occasion the patient took very badly. The shock, however, soon passed off, the pulse falling to 112 in a few hours, and after this she made a perfectly satisfactory and uneventful recovery. The wound, though necessarily septic owing to the escape of the contents of the rectum, gave no trouble, and almost the whole of the anterior part had united when the stitches were removed on the seventh day. The posterior portion where the tube had been healed more slowly and was not closed until six weeks after the second operation, when the patient returned home. The colostomy was then acting once a day, and required nothing more than a simple pad. The latest information is that she is doing extremely well.

The portion of the bowel removed showed a soft carcinomatous growth about 4 inches long, commencing 2½ inches from the anus, and nearly encircling the rectum. The upper limit of the growth was about ½ inch below the level at which the invaginated portion had separated off.

From the satisfactory result obtained in this case it seems reasonable to conclude that Coffey's suggestion is of distinct value and likely to prove useful in suitable cases.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

ASPHYXIA FROM DEFECTIVE SHIP BOARD VENTILATION

BY GILBERT E. BROOKE, L.R.C.P. & S. EDIN., D.P.H.
PORT HEALTH OFFICER, SINGAPORE.

FATAL accidents take place from time to time on board ship as a result of faulty or imperfect ventilation. Generally speaking, these accidents are the result of poisonous and explosive gases from consignments of cargo as for instance ferro-silicon, which when acted on by moisture evolves phosphoretted hydrogen often accompanied by arseniuretted hydrogen. A number of examples of shipping fatalities from this cause will be found in a special report on the subject issued by the Local Government Board in 1909 (Cd. 4958). Occasionally however in the absence of proper ventilation, changes in the normal oxygen and carbon dioxide air content, brought about in various ways, may result in serious mishaps. As far as my experience goes these changes are of two types. A condition may arise in which some of the oxygen in a compartment is used up, while the normal CO₂ content is unchanged, while on the other hand the amount of CO₂ may be much increased at the expense of the existing oxygen.

The first of these two types is, of course, the less dangerous. The following is a good example of it—

An empty oil tank ship arrived in Singapore. Her after cofferdam had been filled with Suez water, most of which had been used, and the compartment had been battened down for about a month. When the compartment was first opened several men who attempted to enter became unconscious. After being rescued and removed to the fresh air they all recovered without further mishap. An analysis of air in the compartment showed that there was no petroleum vapour and that the CO₂ was normal. The oxygen, however, had fallen to 15.4 per cent. The result was therefore merely an oxygen starvation, which, if not too long continued, could be easily recovered from. The only reasonable cause which could be discovered for the condition was a process of rapid oxidation of the bulkhead ironwork (in the presence of closure, heat, and moisture), leading to a large abstraction of oxygen without other chemical action.

With regard to the second type mentioned above, two cases have come to my notice both of which were attended with fatal results.

A ship named the *Merapi* arrived from China on April 25th 1908. When her lower holds were opened up for the removal of cargo two of the ship's crew who attempted to enter the hold fell down insensible. They were removed after a little time, but artificial respiration was tried without success. On analysis the air of the hold showed oxygen 8.6 per cent and CO₂ 11.8 per cent. I was on leave at the time and could, unfortunately, get no particulars as to the ventilation of the compartment nor the composition of the cargo.

The second case was a still more remarkable one. A Dutch steamer, the *s.s. Jacob*, arrived in Singapore on Dec. 22nd, 1915, with general cargo from Amoy and Swatow and 1826 'tween-deck coolie passengers. The passengers were all healthy on arrival and were given pratique at the quarantine anchorage. The ship then proceeded to the inner roads to discharge her cargo. This cargo had been battened down in the lower holds for six days of a tropical voyage. On opening one of the forward holds (No. 2) two of the Chinese crew descended, but immediately fell insensible on the top of the cargo. All attempts to bring them up were unsuccessful, until the hatch cover had been removed for some ten minutes. The men were then apparently dead. Artificial respiration was continued for some time, but without avail. Spaces between cargo-bales enabled me to obtain a sample of air from near the limber boards, which, on subsequent analysis, disclosed the following remarkable figures: Carbon dioxide, 22.55 per cent, oxygen 1.86 per cent, marsh gas, 0.30 per cent, nitrogen, 75.29 per cent. When the hold had been properly aired after an hour or two I was able to go down and make a survey. The air was hot, slightly aromatic but disagreeably acrid. There had been originally two ventilators communicating with that hold. The forward one traversed the 'tween-deck intact and ended as a six foot shaft above the main deck. This shaft was fitted with a fixed mushroom top and could therefore at best only act as an uptake, but would have no action at all in the absence of other ventilating openings or intakes. The second ventilator was situated aft, and, like the first, traversed the 'tween-deck intact, but was then diverted in square section through some cabins and was supposed to open on the upper boat deck. The opening, had however been permanently decked over seemingly for a long time. There had therefore been a condition of air stasis for six or seven days in a hold three quarters full of cargo and at a temperature probably increased by wild heat to over 90° F.

Under such circumstances the composition of the cargo was the important question. A few sacks of soy beans and cooked rice comprised the smaller portion. There were also 277 baskets of garlic and over 1000 large wooden tubs of fresh oranges. The rest of the space was occupied with bales of Chinese paper and baskets of fowls' eggs. The replacement of all the oxygen by carbon dioxide must have been brought about by respiration of the oranges and garlic in the absence of any ventilation, and the high temperature was probably a contributing factor of importance.

SINGAPORE

A CASE OF ADVANCED INTRA ABDOMINAL PREGNANCY

BY B. RADDALE VICKERS, M.B., B.S., L.D.S.
IN CHARGE OF LATAI MISSION HOSPITAL, WUCHOW, KANGSI PROVINCE, CHINA.

In view of the rarity of abdominal pregnancy confined to the later months, it is worth while recording the following case recently treated in Wuchow, Kwangsi Province, China.

The patient, a boat-woman aged 32, appeared at the clinic on Nov. 23rd 1915 complaining of a lump in the abdomen.

and giving the following history. Fever and chills in the fourth moon, swelling of abdomen began a month ago, occasional pain in the abdomen. Bowels open daily with hard stools. Menstrual history. Had had two children, 20 and 19 years ago, no pregnancy since then. The menses were regular until the third moon of this year (April-May), then nothing until the sixth moon (July), when the flow appeared twice. The same happened in the seventh moon, since when nothing up to date. Premenstrual pain for about a year, no leucorrhœa.

Abdominal examination—A visible tumour in the lower abdomen, roughly median in position. Faint linea nigra present, also a number of cautery marks in the left iliac region, which part she said was the most painful. The tumour came up from the pelvis, was irregular, movable, and very hard, manipulation causing more or less pain. Percussion dull, splenic area resonant. The upper limit of the mass was about at the level of the umbilicus, and an "edge" was palpable to the left of this.

Vaginal examination—Great hypertrophy of lips of cervix, which was very soft. There was a knob in Douglas's pouch, very hard, and connected with the abdominal lump. The uterine sound passed from 4½ to 5 inches. The main mass seemed to be behind the uterus which was deflected towards the right side.

The patient was admitted to hospital on Nov 29th, 1915. After admission she had a good deal of pain in the tumour, and six days subsequently began to have a pale bloody discharge from the vagina (? menses). On Dec 7th she passed three fleshy "clots" one of which I saw, 1½ in square and 1 in thick, not unlike decidua membrane. On Dec 8th this note was made: "On examination of the abdomen this morning I noticed immediately that the mass was moving inside in a manner suggestive of vigorous fetal movements. These continued incessantly, and further examination showed that the irregularities of the tumour might well be fetal small parts. Careful auscultation revealed a foetal heart beating at 168 per minute heard in the left iliac region immediately above and external to the innermost of the cautery marks. Patient says the tumour has been moving for over a month and the movements are accompanied by pain." Dec 10th "Upper part of tumour is to-day well above umbilicus. Cannot define it well because of the tenderness and cannot make out the placental mass."

On Dec 10th with the assistance of Dr Haves, I operated. Dr Leavell giving the chloroform. An incision 5 in long was made in the middle line above and below the umbilicus. As soon as the peritoneum was incised the intestines and omentum presented, and a certain quantity of yellowish fluid escaped. The intestines had lost their gloss and were studded in parts with little nodules from a chronic peritonitis they were not matted together, though here and there flakes of lymph were seen. While the bowel was being replaced a loop of umbilical cord extruded itself from the lower end of the wound. On holding apart the abdominal wall the child was visible and was extracted without much difficulty the head causing a little delay as compared with other parts. The position was dorso-anterior, with the feet in the right false pelvis and the head up in the direction of the spleen. The child was not in any sac but the head was enclosed in a pouch which seemed to grasp its neck and caused a moment's delay in delivery though there was no definite membrane found. The cord having been clipped and severed was traced into the placenta, which was found to be large and attached to the right side of the pelvis and the posterior surface of the uterus. In view of the risk of serious hæmorrhage from the placental sinuses it was decided to remove the uterus and appendages *en masse* with the attached placenta. As the uterus had also a myoma this proceeding was less undesirable than it might otherwise have been. Supravaginal amputation was therefore performed with the removal of the right appendages and left tube the left ovary being left *in situ*. Considerable hæmorrhage was encountered from the placental vessels as the tissues were more friable than is the case with normal intra uterine placenta. As the patient had lost a good deal of blood and the general condition was dangerous no attempt was made to unite the opening in the posterior parietal peritoneum. This was because the previous manipulations in this area had led to much bleeding and it was feared that the introduction of the needle for sitching might restart the trouble. A tube and gauze drain were left down to the bare area and the anterior abdominal wall was closed. The operation took exactly three hours and as its close the patient's pulse had recovered somewhat, being fairly strong at 116 per minute. The child was covered on its back, shoulders and arms with lanugo being apparently about eight months old. It was revived after delivery and lived a few hours. Sex female. On examination of the extracted uterus &c I was found that the right tube could be traced for a distance of about one inch and was then lost on the placenta. The placental attachments to the womb's posterior surface were of such a nature that they could have been broken down without severe hæmorrhage but previous to the removal it was impossible to know this. The uterine

cavity contained a ragged decidua, and in its anterior wall was an interstitial myoma of the size of a walnut. The right ovary was enlarged. It is noteworthy that this child was to all intents free in the peritoneum without any enclosing sac of amnion and not surrounded by any appreciable amount of fluid.

Thirty-six hours after operation the temperature rose to 103.2° F. This was not surprising in view of the manipulations and the large bare area. By proctocolysis and hypodermoclisis, however, the danger was averted, and the untoward symptoms gradually disappeared. The subsequent progress was good but complete closure was delayed by the infection of some deep ligatures which necessitated continued drainage. Ultimately the patient left the hospital completely well on Jan 27th, 1916. (It was interesting that on Dec 24th to 27th the breasts became enlarged and knotty, with secretion of a watery milk.)

Reconstructing the history of this morbid condition, it appears that the patient became pregnant about the third moon, the pregnancy occurring in the right tube. Amenorrhœa followed, but by the sixth moon the sac had grown large enough to require more space, and ruptured the tube, this was accompanied by uterine hæmorrhage. The internal hæmorrhage was not very severe and though the sac itself was ruptured that part of the chorion which was destined to form the placenta was not damaged sufficiently to overcome its vitality. The embryo continued to grow, the placenta forming around the site of rupture.

The foetus was in the nature of a foreign body free in the peritoneal cavity and set up a chronic low peritonitis, as evidenced (1) pathologically, by the granular intestinal peritoneum and free peritonitic fluid, and (2) clinically by the tenderness on palpation and pain on foetal movements. (There is no reason to suppose that intraperitoneal foetal movements, apart from inflammation, would of themselves cause pain, any more than the physiological movements of intestinal loops cause pain in normal individuals.)

The irregular hæmorrhage in the sixth and seventh moons is thus accounted for. The passage of decidua while in hospital may not unreasonably be attributed to the exploration by sound a few days previously. In fact, it seems as if a "labour" had supervened, but that the placental circulation had not immediately ceased, as is usually the case.

The question which I have not been able to solve is: Why should the foetal movements have varied so greatly at different times? When I saw the patient in the dispensary and again in the hospital abdominal inspection and palpation aroused no suspicion, but on Dec 8th the moment the abdomen was uncovered one could not help seeing the furious "kicks" continually going on, and yet having seen and felt them, the next day in prolonged palpation I failed to detect any movement whatever, though the event proved that the child was not dead.

ROYAL SOCIETY OF MEDICINE

SECTION OF OBSTETRICS AND GYNÆCOLOGY

Exhibition of Case and Specimens—Hamatoma of the Abdominal Wall—Abdominal Pregnancy—Acute Hepatic Ictæmia Complicating Pregnancy and Labour

A MEETING of this section was held on June 8th, Dr M. HANDFIELD-JONES, the President, being in the chair.

Mr JOHN D. MALCOLM showed a case of Strangulation of the Uterus by Torsion of the Body on the Cervix. While rotation of the whole uterus with an ovarian or uterine tumour is not very uncommon, the displacement being at most something over half a revolution Mr Malcolm stated that he had never seen complete arrest of the blood supply from this cause. The patient was a rather frail woman, aged 70 married, but never pregnant, who on Nov 3rd complained after dinner of pelvic pain. Next morning she could not get up afterwards because the pain became so intense and it was then accompanied by vomiting. Towards evening the temperature rose to 101° F. That night a hard round pelvic tumour was found median in position, and about 4 inches in diameter. Behind this and also in

the middle line lay an elongated irregularly oval mass, measuring apparently about 3½ inches from above downwards by 1½ inches from side to side. This was fairly soft but of uneven consistence. It seemed to be attached to the hard mass in front, and there was a soft short cervix uteri below. The rectum was firmly compressed, but the abnormal parts seemed to be slightly movable as one mass in the pelvis. They were very tender and therefore seemed larger and more fixed than they really were. It was known that a fibromyoma existed before the patient's menstruation ceased, and it was easy to surmise that something had twisted. On opening the abdomen a fibromyoma was seen attached to the left anterior upper part of the uterus. This and the uterine body had revolved one full turn on the cervix, the lower end of the body being so tightly twisted that the parts above were of a deep blue black colour, and although it was only 16 hours after the pain became severe and about 28 from its first onset, the conditions caused a distinctly offensive odour. Supracervical hysterectomy was performed, and the left ovary and Fallopian tube, which were raised by the new growth above the constriction, were taken away. The right ovary and the greater part of its tube were below the constriction and were not removed. Considerable trouble from flatulent distension followed the operation, but otherwise recovery was good although slow. The specimen exhibited by Mr. Malcolm showed a uterine body as big as that of a woman in the prime of life, but enlarged by congestion. The softness of its tissue, due to senility, evidently facilitated the attenuation necessary to make it sufficiently narrow to become strangulated by torsion.—Dr. CURTHER LOCKYER referred to the following cases of acute torsion—1 Poth's case shown in Berlin in May, 1913. The patient was aged 56. She had suffered from severe abdominal pain for 21 years, and was known to have a large abdominal tumour. The abdomen contained blood stained fluid. A pedunculated subserous myoma with a twisted pedicle was removed, and then the uterus itself was found to be twisted upon its neck through 360 degrees from left to right. 2 In August, 1914, Dr. T. W. Eden and Dr. Lockyer operated on a case in which a similar condition was discovered. The large myomatous uterus was blue black in colour, and both appendages were engorged with blood and thrombotic. 3 Steinbuechel's case, in which severe internal hemorrhage resulted from rupture of one of the vessels which was severed during torsion of the pedicle. 4 Grunert's case, where a moderate degree of torsion of the uterine body (90 degrees) led to very acute symptoms simulating the acute torsion of an ovarian cyst. 5 Jolly's case, in which a torsioned myomatous uterus became impacted in the pelvis and led to displacement and blocking of the ureters, double surgical kidney and death from uræmia. Dr. Lockyer thought that the causation of torsion of the uterine body was still a subject for speculation. When, as in Poth's case, the pedicle of a large myomatous uterus became twisted it was not difficult to understand that a small uterine body lying below might share in the process, especially since it is acknowledged that once torsion has taken place it is apt to be progressive. In a case like Mr. Malcolm's where the tumour had a wide attachment to the uterus it must be assumed that in trying to rise out of the pelvis it met with resistance, to overcome which rotation of the tumour and of the uterine body was brought into play. The fact that these cases occurred in women over 50 years of age was noteworthy.

Dr. F. J. MCCANN showed (1) A specimen of Pregnancy in a Large Fibromyomatous Uterus, and (2) a specimen of Soft Fibroma of the Vaginal Wall.

Dr. H. RUSSELL ANDREWS read a short communication on three cases of Hematoma of the Abdominal Wall. 1 A patient eight months pregnant was admitted to the London Hospital very ill with pulse rate 135 per minute temperature 101° F at night, respirations 28-36 per minute with severe cough and much dyspnoea. The pregnant uterus was felt in the left half of the abdomen while the right half was filled by a large exquisitely tender tumour. A premature stillborn child was born 30 hours after admission. The patient's general condition was such as to contra-indicate abdominal section until several days after her admission. A diagnosis of ovarian cyst with localised peritonitis was made. At the operation the tumour was found to be a hematoma containing nearly 2 lb of blood between the right transversalis muscle and the transversalis fascia. 2 A patient was sent into the London Hospital with a diagnosis

of twisted ovarian tumour. For two weeks she had had a painful swelling in the left side of the abdomen after carrying a pair of steps upstairs. Dr. Andrews made a diagnosis of hæmorrhage into, or round, a desmoid tumour in the left rectus. The tumour proved to be a hematoma in the left rectus muscle spreading out a short distance between the transversalis muscle and the transversalis fascia. 3 A patient under the care of the late Dr. Maxwell had a painful swelling on the left side of the abdomen, which had appeared a week previously with coughing. This swelling was found to be a hematoma, which had apparently originated between the left rectus and tracked outwards. Dr. Andrews referred to four previously recorded cases of hematoma of the abdominal wall. Four of the seven patients were pregnant and four complained of cough.—The PRESIDENT thought that these cases must be very rare, as he had seen only one instance during a somewhat long experience.—Mr. MALCOLM and Dr. ANDREW ROUTH had also each seen one case, the latter in a woman who had for some time had a small umbilical hernia, the ring of which suddenly gave way during a sudden effort, and hæmorrhage took place below the protruding bowel.

Dr. MCCANN read a short communication on a case of Abdominal Pregnancy, probably Primary.

Dr. JOHN PHILLIPS read a paper on Acute Hepatic Toxæmia Complicating Pregnancy and Labour. In bringing the subject forward for discussion he noted that no previous consideration of this complication of pregnancy and labour had ever taken place before this society. He related five cases arising in just over 2000 carefully recorded cases of labour in private practice which presented many similar features and which could be placed in one group. Many of the symptoms were similar to those observed in acute yellow atrophy and late chloroform poisoning. These symptoms were carefully compared, and Dr. Phillips concluded that the disease in his cases was due to an ascending toxæmia of the bile ducts.—The PRESIDENT thought it noteworthy that only five cases of hepatic toxæmia had occurred in a total of 2000 deliveries. He judged from this fact that a special combination of morbid conditions was needed to bring about the storm. Again, the rapid fatality in two of the cases and the milder attack in those which recovered suggested the same idea of varying intensity of combination. In formulating any theory three factors would have to be considered: (1) The changes in the liver cells associated with fatty metamorphosis, (2) the action of toxic substances ascending by way of the bile ducts from the intestine, and (3) the influence of chloroform as a determining cause. He agreed with Dr. Phillips that the mischief was started by intestinal disease and spread along the line of the hepatic vessels and ducts. Fatty metamorphosis and chloroform inhalation were possibly additional factors in determining the onset and severity of the symptoms.—Dr. ROUTH thought the title of Dr. Phillips's paper might be altered to "Toxæmia in Pregnancy Affecting the Liver" for he thought true pregnancy toxæmia began in the liver, for he thought true pregnancy toxæmia began in the cells of the chorionic villi and affected different secreting cells of the glandular organs, according to the type of toxin or the condition of the patient's organs. Most of Dr. Phillips's cases were associated with bacillus coli cystitis and in such cases the liver troubles might be due to ascending intestinal infection by the same organism or by toxins derived from those bacilli.

Dr. HERBERT WILLIAMSON said that thanks were due to Dr. Phillips for focussing attention upon a group of cases which were occasionally met with in practice and which gave rise to a considerable degree of anxiety. He was not, however, able to accept the suggestion that the group of cases reported in the paper constituted a clinical entity. He agreed that they were cases of severe hepatic lesions. Clinical and pathologically observed suggested that during pregnancy the liver appeared to be peculiarly susceptible to the action of toxins, and it was clearly established that the incidence of acute yellow atrophy was much greater in the pregnant than in the non-pregnant state. Dr. Phillips's cases supported the view he (Dr. Williamson) took that given the accepted view, the actual lesions might be produced by a variety of toxic agents such as poisons produced by the tissues of the chorionic villi, poisons produced by the bacillus coli communis or chemical poisons such as chloroform. He thought that all these three groups were represented in the collection of cases reported by Dr. Phillips.—Dr. WALTER GRIFFITH and Dr. FREDERICK HOLLAND also discussed the paper.

Reviews and Notices of Books.

Serums, Vaccines, and Toxins in Treatment and Diagnosis

By WILLIAM CECIL BOSANQUET M.A., M.D. Oxon, F.R.C.P. LOND., Physician to the Charing Cross Hospital, and JOHN W. H. EYRE M.D., M.S. Dunelm., F.R.S. Edin. Director of the Bacteriological Department of Guy's Hospital. Third edition. Illustrated. London: Cassell and Co. 1916. Pp. 456. Price 9s. net.

It is more than six years since we noticed the second edition of this valuable little volume on a very big subject. The intervening period has been so fruitful in research and has witnessed such notable advances in methods of diagnosis and treatment that the authors have found an exhaustive revision necessary, entailing the addition of nearly 100 pages of new matter. A perusal of the book will assure the reader that additions are to be found on nearly every page containing abstracts of recent publications as well as, in most cases, the conclusions drawn by the authors from their own observations. Experience drawn from the present war is still too tentative for sweeping conclusions except in certain particulars. Of the prophylactic use of tetanus antitoxin the confident statement "There is ample evidence that antitoxin proves of greatest service in the prevention of tetanus" takes the place of the hope expressed in the previous edition. And of antityphoid inoculation the authors state in their new edition that the experience gained during the present war forms a striking testimony to the value of antityphoid vaccination as practised in the British army, instead of the faint recommendation of inoculation to persons going into parts of the world where enteric fever is very prevalent. On the other hand, the recent work on the serum or vaccine treatment of tetanus, typhoid and cerebro spinal fever is given with due reserve as to the worth of these methods. With the inclusion of most work of real value we miss the report by Surgeon General H. D. Rolleston on the serum treatment of cerebro spinal fever in the navy. A new chapter, headed "Diseases due to Protozoa," has been introduced containing a useful summary of the principles of chemotherapy, and although admittedly trespassing somewhat outside the domain indicated by the title we agree with the authors that they were justified in its inclusion. Mention of the sulphur and antimony substitutes for organic arsenic compounds brings the subject matter up to quite recent date.

We assume that this new edition of Dr Bosanquet and Dr Eyre's book will be widely used by many who cannot readily refer to original sources. It is therefore the more regrettable that a serious error in the second edition has been allowed in part to creep over into the third. In the second paragraph on the mode of using tuberculin for diagnostic purposes commencing on p. 304, it is correctly stated that Koch recommended an initial dose of 0.001 c.c. or of 0.0001 c.c. in delicate individuals, and a second dose of double the quantity if no reaction takes place. It is then stated "If however no effect is produced by the small doses they may be increased to 0.5 and even to 1.0 c.c., and this final dose may be administered twice in order to make sure of the absence of a reaction." Koch is here credited with having recommended an increase of 500 times or 1000 times the initial dose. Of course, he did nothing of the sort. He recommended an increase of five or ten times only, and the error has occurred in the text from rendering 5 mg. and 10 mg., which are the actual quantities Koch gives as 0.5 and 1.0 c.c. instead of 0.005 and 0.01 c.c. Koch himself laid stress on the fact that 10 mg. or 0.01 c.c. of Old Tuberculin was the largest amount that could be given without risking a reaction in the non-tuberculous subject and he records having administered 250 mg. or 0.25 c.c. to himself and been rewarded with a severe and painful reaction. The same error is present in all the figures given in the third paragraph. Junker advised a series of 1/10, 5/10, 1/5 and 10 mg. or 0.0001, 0.0005, 0.001, 0.005 and 0.01 c.c. and not the hundredfold doses stated in the text. Löwenstein and Kauffmann's valuable suggestion to give a series of four equal doses of 0.0002 c.c. is rendered as four doses of 0.02 c.c., Röpke is similarly misrepresented and so it goes on. Only Trudeau's dosage has been correctly revised, and the authors' conclusion that

one thousandth of a cubic centimetre is probably the largest dose which should ever be administered for diagnosis, and their recommendation of the series 0.0001, 0.0002, 0.0005, and 0.001 c.c. as the most suitable are not widely different from those of the authorities whom they misrepresent. An early opportunity will doubtless be taken of correcting errors which, if followed might have dangerous results.

Apart from this blemish and from a tendency to retain for completeness sake preparations no longer used for which oblivion would have been appropriate, we should like to emphasise our high opinion of this manual. The language throughout the book is clear, the explanations simple and lucid, original references are supplied to all important work, and the reader is given a sound basis for his knowledge and opportunity of readily pursuing it further.

Monographs on Biochemistry. The Respiratory Exchange of Animals and Man.

By AUGUST KROGH Ph.D., Reader in Zoophysiology, University of Copenhagen. With diagrams. London: Longmans, Green, and Co. 1916. Pp. 173. Price 6s. net.

THE editors of this series continue their praiseworthy task of supplying monographs on specific physiological problems by authors who themselves have been active workers on the several subjects. In the latest monograph, which is before us, Dr Krogh, of Copenhagen points out that the subject of the respiratory exchange of animals belongs rather to the domain of chemical physiology than to that of physiological chemistry. The book deals with very few substances, and with their quantities, not their qualities and the reader will find it to be an excellent résumé and exposition of a difficult subject including descriptions of technique which differ somewhat from that employed in other branches of biochemical work.

The following are some of the problems dealt with. The physiological significance of the exchange of oxygen and carbonic acid including the carbon balance, respiratory quotient, and direct and indirect calorimetry, methods for measuring the respiratory exchanges, the exchange of nitrogen, hydrogen methane, ammonia and other gases of minor importance, standard metabolism and the influence of internal factors on it and the variations in standard metabolism during the life cycle of the individual, the influence of chemical and physical factors upon the respiratory mechanism, and lastly the respiratory exchange in different animals. The author points out that in studying the respiratory exchange of an animal we have to do with a quantity which is variable in the extreme. In man the maximum respiratory activity is 10 to 20 times the minimum in one and the same individual, and in many lower animals the maximum may be several hundred times the minimum. The factor which is of paramount importance in determining the metabolism is the functional activity. This shows one of the difficulties of obtaining the standard metabolism of an organism. To pharmacologists the chapter on the influence of various drugs will prove attractive. The old view of Pflüger (1873) that the animal cell itself determines its own respiratory exchange has recently been contested by Thunberg (1905) who maintains that the oxidative processes must increase with increased oxygen pressure and gradually approach a maximum. Another view, that of Moleschott (1855) that the respiratory exchange of animals is higher in light than in darkness must, it appears be given up—the most recent experiments show that no measurable effect of light could be detected, but even this does not satisfy the author, who suggests that experiments be made on hyaline aquatic animals suitably narcotised to ensure standard conditions. The chapter on hibernation in mammals is interesting. Not a single bird manifests this phenomenon.

A valuable bibliography of nearly 16 pages gives some idea of the 'intensive' study devoted to this limited yet fundamental problem in chemical physiology. Every physiologist must feel that Dr Krogh has rendered a notable service by presenting in a readable and easily assimilable form the results of his research.

LIBRARY TABLE

A Contribution to a Knowledge of Canadian Ticks. By GORDON HRWITT D.Sc. Scientific Contributions from the Entomological Branch Department of Agriculture Ottawa. Reprinted from the Transactions of the Royal Society of

the middle line lay an elongated irregularly oval mass, measuring apparently about 3½ inches from above downwards by 1½ inches from side to side. This was fairly soft but of uneven consistence. It seemed to be attached to the hard mass in front, and there was a soft short cervix uteri below. The rectum was firmly compressed, but the abnormal parts seemed to be slightly movable as one mass in the pelvis. They were very tender and therefore seemed larger and more fixed than they really were. It was known that a fibromyoma existed before the patient's menstruation ceased, and it was easy to surmise that something had twisted. On opening the abdomen a fibromyoma was seen attached to the left anterior upper part of the uterus. This and the uterine body had revolved one full turn on the cervix, the lower end of the body being so tightly twisted that the parts above were of a deep blue-black colour, and although it was only 16 hours after the pain became severe and about 28 from its first onset, the conditions caused a distinctly offensive odour. Supracervical hysterectomy was performed, and the left ovary and Fallopian tube, which were raised by the new growth above the constriction, were taken away. The right ovary and the greater part of its tube were below the constriction and were not removed. Considerable trouble from flatulent distension followed the operation, but otherwise recovery was good although slow. The specimen exhibited by Mr. Malcolm showed a uterine body as big as that of a woman in the prime of life, but enlarged by congestion. The softness of its tissue, due to senility, evidently facilitated the attenuation necessary to make it sufficiently narrow to become strangulated by torsion.—Dr. OUTHBERT LOCKYER referred to the following cases of acute torsion.—1 Poth's case shown in Berlin in May, 1913. The patient was aged 56. She had suffered from severe abdominal pain for 21 years, and was known to have a large abdominal tumour. The abdomen contained blood stained fluid. A pedunculated subserous myoma with a twisted pedicle was removed, and then the uterus itself was found to be twisted upon its neck through 360 degrees from left to right. 2 In August, 1914, Dr. T. W. Eden and Dr. Lockyer operated on a case in which a similar condition was discovered. The large myomatous uterus was blue black in colour, and both appendages were engorged with blood and thrombotic. 3 Steinbuechel's case, in which severe internal hemorrhage resulted from rupture of one of the vessels which was severed during torsion of the pedicle. 4 Granert's case, where a moderate degree of torsion of the uterine body (90 degrees) led to very acute symptoms simulating the acute torsion of an ovarian cyst. 5 Jolly's case, in which a torsioned myomatous uterus became impacted in the pelvis and led to displacement and blocking of the ureters, double surgical kidney and death from uremia. Dr. Lockyer thought that the causation of torsion of the uterine body was still a subject for speculation. When, as in Poth's case, the pedicle of a large myomatous uterus became twisted it was not difficult to understand that a small uterine body lying below might share in the process, especially since it is acknowledged that once torsion has taken place it is apt to be progressive. In a case like Mr. Malcolm's, where the tumour had a wide attachment to the uterus it must be assumed that in trying to rise out of the pelvis it met with resistance, to overcome which rotation of the tumour and of the uterine body was brought into play. The fact that these cases occurred in women over 50 years of age was noteworthy.

Dr. F. J. McCANN showed (1) A specimen of Pregnancy in a Large Fibromyomatous Uterus, and (2) A specimen of Soft Fibroma of the Vaginal Wall.

Dr. H. RUSSELL ANDREWS read a short communication on three cases of Hematoma of the Abdominal Wall. 1 A patient eight months pregnant was admitted to the London Hospital very ill with pulse-rate 135 per minute temperature 101° F at night, respirations 28-36 per minute with severe cough and much dyspnoea. The pregnant uterus was felt in the left half of the abdomen while the right half was filled by a large, exquisitely tender tumour. A premature stillborn child was born 30 hours after admission. The patient's general condition was such as to contraindicate abdominal section until several days after her admission. A diagnosis of ovarian cyst with localised peritonitis was made. At the operation the tumour was found to be a hæmatoma containing nearly 2 lb. of blood between the right transversalis muscle and the transversalis fascia. 2 A patient was sent into the London Hospital with a diagnosis

of twisted ovarian tumour. For two weeks she had had a painful swelling in the left side of the abdomen after carrying a pair of steps upstairs. Dr. Andrews made a diagnosis of hæmorrhage into, or round, a desmold tumour in the left rectus. The tumour proved to be a hæmatoma in the left rectus muscle spreading out a short distance between the transversalis muscle and the transversalis fascia. 3 A patient under the care of the late Dr. Maxwell had a painful swelling on the left side of the abdomen, which had appeared a week previously with coughing. This swelling was found to be a hæmatoma, which had apparently originated between the left rectus and tracked outwards. Dr. Andrews referred to four previously recorded cases of hæmatoma of the abdominal wall. Four of the seven patients were pregnant, and four complained of cough.—The PRESIDENT thought that these cases must be very rare, as he had seen only one instance during a somewhat long experience.—Mr. MALCOLM and Dr. AMAND ROUTH had also each seen one case, the latter in a woman who had for some time had a small umbilical hernia, the ring of which suddenly gave way during a sudden effort, and hæmorrhage took place below the protruding bowel.

Dr. McCANN read a short communication on a case of Abdominal Pregnancy, probably Primary.

Dr. JOHN PHILLIPS read a paper on Acute Hepatic Toxæmia Complicating Pregnancy and Labour. In bringing the subject forward for discussion he noted that no previous consideration of this complication of pregnancy and labour had ever taken place before this society. He related five cases arising in just over 2000 carefully recorded cases of labour in private practice which presented many similar features and which could be placed in one group. Many of the symptoms were similar to those observed in acute yellow atrophy and late chloroform poisoning. These symptoms were carefully compared, and Dr. Phillips concluded that the disease in his cases was due to an ascending toxæmia of the bile ducts.—The PRESIDENT thought it noteworthy that only five cases of hepatic toxæmia had occurred in a total of 2000 deliveries. He judged from this fact that a special combination of morbid conditions was needed to bring about the storm. Again, the rapid fatality in two of the cases and the milder attack in those which recovered suggested the same idea of varying intensity of combination. In formulating any theory three factors would have to be considered: (1) The changes in the liver cells associated with fatty metamorphosis, (2) the action of toxic substances ascending by way of the bile ducts from the intestine, and (3) the influence of chloroform as a determining cause. He agreed with Dr. Phillips that the mischief was started by intestinal disease and spread along the line of the hepatic vessels and ducts. Fatty metamorphosis and chloroform inhalation were possibly additional factors in determining the onset and severity of the symptoms.—Dr. ROUTH thought the title of Dr. Phillips's paper might be altered to "Toxæmia in Pregnancy Affecting the Liver," for he thought true pregnancy toxæmia began in the cells of the chorionic villi and affected different secreting or glandular organs according to the type of toxin or the condition of the patient's organs. Most of Dr. Phillips's cases were associated with bacillus coli cystitis, and in such cases the liver troubles might be due to ascending intestinal infection by the same organism or by toxins derived from those bacilli.—Dr. HERBERT WILLIAMSON said that thanks were due to Dr. Phillips for focussing attention upon a group of cases which were occasionally met with in practice and which gave rise to a considerable degree of anxiety. He was not, however, able to accept the suggestion that the group of cases reported in the paper constituted a clinical entity. He agreed that they were cases of toxæmia and that the toxins had evidently produced severe hepatic lesions. Clinical and pathological observation suggested that during pregnancy the liver appeared to be peculiarly susceptible to the action of toxins, and it was clearly established that the incidence of acute yellow atrophy was much greater in the pregnant than in the non gravid state. Dr. Phillips's cases supported the view he (Dr. Williamson) took that given the susceptibility, the actual lesions might be produced by a variety of toxic agents such as poisons produced by the cells of the villi of the chorionic villi, poisons produced by the bacillus coli communis, or chemical poisons such as chloroform. He thought that all these three groups were represented in the collection of cases reported by Dr. Phillips.—Dr. WALTER GRIFITH and Dr. FARLEY HOLLAND also discussed the paper.

These symptoms were carefully compared, and Dr Phillips concluded that the disease in his cases was due to an ascending toxæmia of the bile ducts. —THE PRESIDENT thought it noteworthy that only five cases of hepatic toxæmia had occurred in a total of 2000 deliveries. He judged from this fact that a special combination of morbid conditions was needed to bring about the storm. Again the rapid fatality in two of the cases and the milder attack in those which recovered suggested the same idea of varying intensity of combination. In formulating any theory three factors would have to be considered (1) The changes in the liver cells associated with fatty metamorphosis, (2) the action of toxic substances ascending by way of the bile ducts from the intestine, and (3) the influence of chloroform as a determining cause. He agreed with Dr Phillips that the mischief was started by intestinal disease and spread along the line of the hepatic vessels and ducts. Fatty metamorphosis and chloroform inhalation were possibly additional factors in determining the onset and severity of the symptoms.

—Dr ROUTH thought the title of Dr Phillips's paper might be altered to 'Toxæmia in Pregnancy Affecting the Liver,' for he thought true pregnancy toxæmia began in the cells of the chorionic villi and affected different secreting or glandular organs according to the type of toxin or the condition of the patient's organs. Most of Dr Phillips's cases were associated with bacillus coli cystitis and in such cases the liver troubles might be due to ascending intestinal infection by the same organism or by toxins derived from those bacilli.

—Dr HERBERT WILLIAMSON said that thanks were due to Dr Phillips for focussing attention upon a group of cases which were occasionally met with in practice and which gave rise to a considerable degree of anxiety. He was not, however, able to accept the suggestion that the group of cases reported in the paper constituted a clinical entity. He agreed that they were cases of toxæmia and that the toxins had evidently produced severe hepatic lesions. Clinical and pathological observation suggested that during pregnancy the liver appeared to be peculiarly susceptible to the action of toxins and it was clearly established that the incidence of acute yellow atrophy was much greater in the pregnant than in the non gravid state. Dr Phillips's cases supported the view he (Dr Williamson) took that given the severity of the actual lesions might be produced by a variety of toxic agents such as poisons produced by the epithelial tissues of the chorionic villi, poisons produced by the bacillus coli communis or chemical poisons such as chloroform. He thought that all these three groups were represented in the collection of cases reported by Dr Phillips.

Dr WALTER GRIFITH and Dr FREDLEY HOLLAND also discussed the paper.

think the idea is a good one. According to our analysis we find that this special solac contains 7.24 per cent of fat present in the same highly emulsified and suspended state as is the case with natural milk. The total solids amounted to 15.98 per cent. These results represent, in fact, the composition of cow's milk with the amount of fat doubled. It seems to us to be a valuable fatty food, which on account of its easy assimilability should be of service in cases where rapid nourishment is required and particularly in wasting diseases. It, moreover, possesses a high energy value. Its taste strongly resembles ordinary milk, as does its appearance, it is soft and creamy.

TINTARA WINE

(BURGOYNE AND CO, 5, DOWGATE HILL, CANNON STREET, LONDON, E.C.)

This is a typical Australian red wine, full bodied and of rich colour. It approaches in character, comparing it with European wines, the burgundy of France, and its analysis

gives similar results. The grapes produced in Australia are of a luscious character, and accordingly the product is as a rule, of a generous description. In our opinion these wines in regard to flavour are often more appreciated when slightly diluted with water. The taste then is mellow and quite non acid, and resembles that of the similar French wines closely. Adding water, of course, means thinning the full bodied wine down to one of a more delicate kind. Thin, delicate wines do not, as a rule, bear dilution well. The robustness of this wine is evidenced in the following analysis which we have made. Alcohol by weight, 12.38 per cent, equal to 26.82° proof spirit, and therefore imported under the low rate of duty, extractive matters 3.47 per cent, mineral matters, 0.37 per cent, volatile acidity reckoned as acetic acid, 0.05 per cent, fixed acidity reckoned as tartaric acid, 0.45 per cent, sugar, 0.54 per cent. The mineral matters contained distinct quantities of both phosphates and iron. The wine is the genuine fermented product of the grape, and is thoroughly wholesome.

DIFFERENTIAL STETHOSCOPES

INTEREST in the relative intensities of the heart sounds has revived recently. This has led to many inquiries as to the relative merits of the differential stethoscopes designed by Oertel and by Bock.

The Oertel stethoscope consists of a chest piece to which a metal tube is attached, in this tube there is a slit which can be opened, and the width of the opening can be read on a scale. A second tube slides over the one with a slit, and can make the slit of any length up to 4 cm. To the end of this tube a Y tube is fitted which is attached to the tubes of a binaural stethoscope. The arrangement provides a stethoscope with a window the area of which can be varied at pleasure and measured accurately. The method of using it is to make the width of the slit 1 mm., and then slide the outer tube towards the graduated end until the slit is covered completely. The chest piece is then applied over the apex of the heart and the slit uncovered until the first sound cannot be heard. On shortening the slit the sound is heard again, the length of the slit when the first sound is just lost is noted. The slit is once more covered by the sliding tube and then the chest piece is transferred to the aortic site and the slit uncovered again until the second sound is just lost. The length of the slit is noted again. In normal cases the size of the window necessary for the first sound at the apex to be lost is twice that required to prevent the second sound at the base reaching the ears. If the heart is beating vigorously, and making very loud sounds, the slit must be opened to 2 or more millimeters. However loud the heart sounds, their

The Oertel stethoscope

intensities can be measured by this instrument because not only does sound escape through the window but also external sound is admitted which overpowers the sound of the heart. This makes it obvious that for successful results the instrument must be used in a quiet room or in one with a constant noise.

The Bock differential stethoscope depends upon a different principle. It consists of a conical chest piece attached to a circular box which is divided into two compartments by a thick metal diaphragm which is pierced by a small hole. Into this hole a cone of metal can be inserted until the aperture is completely closed. When the hole is closed, air borne sounds are stopped. In a well made instrument with the diaphragm set correctly the screw moving the cone turns quite easily until the hole is completely closed. If adjusted badly the screw becomes stiff some distance before it comes to a stop. The pointer should be set at 100 when the hole is closed. The method of using the instrument is by opening the aperture by one complete revolution of the screw placing the chest piece over the apex of the heart and turning the screw until

The Bock stethoscope

the first sound is no longer heard. The position is noted, the average position is 80. The pointer is turned back again to about 10 the stethoscope is applied to the aortic site, and then the pointer turned until the second sound is lost. This occurs on the average at about 60. That is to say, the intensity of the first sound at the apex is audible when the hole in the diaphragm is half the size of that necessary for the conduction of the sound produced by the second sound over the aortic site. Emphysema and a thick chest wall diminish the amount of sound conducted but do not alter the ratio. Sometimes the heart beat is so vigorous that it can be heard when the hole is closed and the pointer is at 100. This is due to conduction through the solid part of the stethoscope. To overcome this which is a rare event a felt ring may be interposed between the stethoscope and the chest wall or some poor conductor of sound introduced between the instrument and the rubber tubes. In order that observations of any value shall be obtained the sound must be air borne and not transmitted through solids.

In my experience the Bock stethoscope has proved the more useful because it can be used in comparatively noisy surroundings and there is but a small percentage of hearts in which the sounds are conducted when the diaphragm is closed. The Oertel stethoscope can compare intensities however vigorous the heart but for accurate work it requires an absolutely quiet room. Messrs Allen and Hanbury of Wigmore Street London W have made satisfactory Bock stethoscopes and Messrs Dowd & Co of St Thomas Street S.E. are making both.

Military Medical Home Service

THE demand for medical officers in the army still continues acute, though the number of certificates of enrolment issued by the Central Medical War Committee is now considerably over 4000, while commissions have been posted at an average of over 40 a week for nearly a year. When, leaving our huge navy out of count, the size of our armies at home and abroad is considered, and when we remember the enormous scope of the operations entailed upon the Allies by their widely separated fronts, there should be no surprise either that the medical profession should be numerically strained by the circumstances, or that at any moment an excess of medical officers may exist at one place coincident with a demand at another place. The categorical statements of the Director General of the Army Medical Service, as well as the detailed information which has gradually reached the country from the various seats of war have we think, dispelled the idea that our army has been hitherto rather enjoying a plethora than resenting a shortage of medical officers. We are glad to notice that statements to this effect have ceased to be made in responsible quarters, and this should have an effect upon chattering in Parliament.

To meet the acute calls for medical officers with the army vigorous steps have been taken in many directions by the Central Medical War Committee and the other committees recognised by the State as responsible for the supply of medical officers to the Navy and Army. The personnel of the medical profession in England and Scotland has been scrutinised, local and educational authorities have dispensed with the services of many of their officials, and all over the country there are districts which have been gravely depleted of medical men. And as the urgent demand yet remained unsatisfied, some believed that a breaking point had been reached, when a wise decision not to limit the offer of commissions in the Royal Army Medical Corps to medical practitioners under 45 years of age was arrived at. Many Territorial medical officers and members of *à la suite* staffs at hospitals were, of course serving in the Royal Army Medical Corps at a more advanced age, but the offer of commissions to other practitioners did not until a few days ago extend to those who were more than 45 years of age. Now, under altered circumstances, an appeal is made for men to accept commissions in the Royal Army Medical Corps, being between the ages of 45 and 55. The military medical service of these middle-aged officers will be at home and they will be employed especially to free the younger medical men, of whom every one who

can possibly be spared should be serving with the armies in the field. The older medical officers will be employed with troops which are not intended to go abroad, and we are certain that they can meet all the requirements of any army prepared and retained in these islands against the risks of invasion. The hospitals staffed by the men of over 45 would be in perfectly safe hands, especially as here the part-time man can be employed, as he can be in the garrisons of the ports and military stations.

It is impossible to estimate how large a number of medical practitioners there may be in the country between the ages of 45 and 55 who are available to take whole time commissions with the Royal Army Medical Corps, but the information possessed by the Central Medical War Committee is now of very precise and detailed character, so that in any given locality the needs of the community can be carefully watched—far more carefully, indeed, than at one time seemed possible. In these circumstances the supply of middle-aged men to take whole time commissions in the Royal Army Medical Corps who are prepared to serve with military units anywhere in the British Isles, and who can be spared from the civilian community in which they practise, ought, we think, to be forthcoming. In our belief there are a good many medical men who fall within this category and who will be very pleased to avail themselves of the opportunity thus given of serving their country, and when they present themselves in substantial numbers there will, it seems to us, be very little excuse for the retention of the younger officers in this country. They will also leave the garrison duty for part time men, an important point, as it is one of the many criticisms to which the Army Medical Service has been subjected that not sufficient use has been made of the part-time man. As a matter of fact, the local nature of the help that he can offer is a bar to his employment save in certain capacities.

Alimentary Rest in Diabetes

THE treatment of diabetes by fasting is not a new one. GUELPA strongly advocated it on the ground that the disease was due to alimentary toxæmia. His method yielded good results, although the theory on which it is based is not necessarily correct, and indeed is not generally accepted. He recommended cautious return to the usual diet after the fast, although he did not lay down a definite plan for doing so. VON NOORDEN interpolated days of fasting and also days of vegetable and egg diet, but here, again, there was no definite plan of building up the diet after such days. ALLEN in America, made a decided advance in our treatment of diabetes by making the fast the first step and following it up by a scheme regulated by urinary analysis. Briefly, the method is that the patient should fast till free from sugar. He is allowed to drink water freely, and can take tea, coffee, and clear meat broth as desired. When the 24 hour specimen of urine is

free from sugar 150 grammes of vegetables containing not more than 5 per cent of carbohydrates are added, and then 5 grammes more are added every day until 170 grammes are reached, the intake is then increased by 5 grammes every other day, foods richer in carbohydrate being gradually added, until bread is reached, unless sugar appears or the tolerance reaches 3 grammes of carbohydrate per kilogramme of body weight. When the urine has been free from sugar for two days three eggs are added, equivalent to 20 grammes of protein, and thereafter 15 grammes daily in the form of meat until the patient is receiving 1 gramme of protein per kilogramme of body weight, or, if the carbohydrate tolerance is nil, only $\frac{1}{2}$ gramme per kilogramme. Fat, other than that contained in the eggs and meat, is only added when this point is reached, and then 25 grammes of fat are added daily until the patient ceases to lose weight or receives not more than 40 calories daily per kilogramme of his weight. If sugar returns, fasting is resumed for 24 hours or until the urine is free from sugar. The diet is then increased twice as quickly as before, but the carbohydrate is not allowed to exceed half the former tolerance until the urine has been free from sugar for two weeks, and it should not then be increased more than 5 grammes per week. He also advised that when the tolerance for carbohydrate is less than 20 grammes of carbohydrate fasting should be practised one day in each week. When the tolerance is between 20 and 50 grammes vegetables containing 5 per cent of carbohydrates and one half the usual quantity of protein and fat are allowed on one day in the week instead of the fast. If the tolerance is more than 100 grammes of carbohydrate, the intake of carbohydrate is merely halved one day each week.

As often happens, different observers have been reaching a somewhat similar conclusion independently by another route. GARROD and GRAHAM have mapped out a plan, largely by observations on the sugar content of the blood. Their method is less drastic, and therefore easier for the patient. They do not make him fast for more than 48 hours, even if the urine still contains some sugar. Then two days of VON NOORDEN'S vegetable and egg diet follow. After this the protein intake is gradually increased. Thus 2-3 oz. of ham and 3 oz. of fish are added after the vegetable and egg days. Next day 3 oz. of meat are substituted for the fish. Another fast is advised at the end of three to four weeks if sugar is still present. In both methods the diet is cautiously pushed up, but while ALLEN'S plan involves a longer fast, that of GARROD and GRAHAM demands more prolonged abstinence from starchy foods. LANGDON BROWN has combined the two procedures by testing the tolerance of the patient to potatoes soon after the meat stage is reached if the patient is then free from sugar. The tolerance of a number of carbohydrate foods is tested in succession, such as Jerusalem artichokes, green peas, apples, and milk. In this way a varied diet can be arrived at fairly quickly, and as individual tolerance to various carbohydrates differs, the offending item in the diet can speedily

be detected. Attention has been focussed on these fasting procedures by the recent discussion opened by Dr O. LEXTON at the Therapeutical Section of the Royal Society of Medicine, when Dr E. I. SPRIGGS reported on the experience gained at Duff House. It was generally agreed by the participants in that debate that the milder cases in later life usually respond rapidly to some such method of fasting. As to the more severe cases, it may be possible to free the urine from sugar for a time but sometimes at too high a cost for the general well being of the patient. Even in the severer cases, however, a modified fasting plan, not on such drastic lines as ALLEN'S, will probably help more than any treatment hitherto followed.

The influence of fasting on acidosis in diabetes is interesting and rather unexpected. Whereas fasting causes some acidosis in a healthy individual, it diminishes acidosis in diabetes. But then the acidosis in diabetes reaches a much higher figure than is ever met with in healthy persons. What appears to happen is that the slight acidosis of starvation continues in the fasting diabetic, but the dangerous toxic acidosis is greatly lessened. This points to the high degree of acidosis in diabetes being caused by the lavish use of proteins, and possibly fats, in the old-fashioned strict diabetic diet. Instead of saying that because a patient cannot assimilate carbohydrate therefore he must take more protein and fat, we must conclude that because his tolerance for carbohydrate is low it is not safe for him to indulge in an unlimited amount of other foods in the absence of carbohydrates. In other words, a diet carefully balanced at a lower level is better than a lopsided diet. On such a plan as this coma is much less likely to occur than on the old method, and alkalis will not be found so necessary. While it is by no means true that fasting procedures are a panacea in diabetes, it is true that a short fast followed by careful graduation of the diet to the assimilative power of the individual is a decided advance on any treatment hitherto introduced. This can be said without hesitation although the method has not been employed long enough yet for us to gauge its ultimate effect.

ROYAL MICROSCOPICAL SOCIETY.—At a meeting of the Royal Microscopical Society held on June 21st Miss G. Lister, F.L.S. made a communication on the life history of Mycetozoa with special reference to Ceratomyxa, in which she referred to the work of Dr Jahn of the Berlin University proving that the amœbæ produced by division of the swarm spores united in pairs as gametes to produce zygotes from which the plasmodia grew. The nuclei of the zygotes had twice as many chromosomes as the nuclei of the gametes. In Ceratomyxa Dr Jahn was the first to observe the division of nuclei in the young sporophores prior to spore-formation; this was found to be a reduction division and took place during the "network" stage of the maturing sporophore. To illustrate these observations lantern slides taken from the preparations lent by Dr Jahn were shown on the screen, as well as a series of slides showing the most striking forms of sporangia met with among the Mycetozoa. Microscopical preparations and drawings illustrating the development of Ceratomyxa and other Mycetozoa were exhibited by Miss Lister and also a number of drawings and specimens of the principal genera.

Annotations.

No quid nimis "

MILK PROBLEMS

THE issue of a work¹ which on the authority of the Medical Research Committee (National Health Insurance) gives a general view of the state of knowledge on the subject of milk in its relations to public health will attract considerable attention, it may do much to clear the air and help us in regard to the problems still ahead. Milk problems are full of difficulty, and it is well to have before us the data in a collected form, which will enable us to appreciate exactly the position. Such a stocktaking is necessary from time to time in many matters where public considerations and scientific procedures meet, and the Medical Research Committee were well advised to choose the milk question as one of the first importance to elucidate, so far as researches and experience have gone. With this object in view they invited Dr Janet E Lane Claypon, assistant medical inspector under the Local Government Board—who, our readers may remember, made valuable reports upon certain portions of the subject in 1911—to collect all the known materials and to make any comment which her wide experience enabled her serviceably to do. It is quite obvious that with the ominous position of infant mortality, when war also is sacrificing lives on a very serious scale, particular attention should be directed to nutritional questions in regard to milk the replies to which may save thousands of infant lives. Infant nutrition needs to be more seriously taken in hand than ever before, and it is somewhat of a reproach to our scientific observers that the present state of our knowledge is not more satisfactory. We know that infant mortality bears a decided relationship to methods of defective feeding, but we are still in need of more accurate information in combating the waste of life from this cause. Physiology, chemistry, bacteriology, and other branches of science have been equally appealed to for assistance, and a certain amount of real practical help has been furnished, but we still lose too many children from what, for want of a better name, we call malnutrition. When it is considered that milk is merely an emulsion of fat, associated with proteins, carbohydrate and mineral salts, the constitution of which is definitely known, the physiological chemistry would appear to be simple. It is not, however, the chemistry alone of milk that is concerned, for milk is not made in the chemical factory, but is the product of a highly organised mechanism in which so many vital factors are concerned. Dr Lane Claypon is inclined to discount any vitalistic theory in regard to the efficiency of natural milk as a constructive in infant feeding. Thus in reviewing the subject she refers to the "so called" biological properties of milk, to the "alleged" production of Barlow's disease and rickets by the use of heated milk for infants, and to vitamin theories which give results that are "somewhat fragmentary." But she admits that milk contains substances of (at present) unknown composition which are essential for the life of the animal

where milk is the sole dietary, adding that there is no evidence to show that these substances are destroyed by boiling, especially when the heat is not applied for prolonged periods and when a temperature not exceeding boiling point is used. The loss of vitamins, she says, if it occurs, is evidently not sufficient to affect the nutritive value of milk, "as has been abundantly shown in the preceding chapters." This statement in defence of boiled milk would appear to indicate that Dr Lane Claypon regards the retention of vitamins intact as important and that no objection can be made to boiling inasmuch as this process does not destroy these substances. The report threatens to revive the whole controversy of the merits and demerits of boiled milk, in connexion with which, amongst other matters, the facts collected in this volume give valuable evidence. It is noteworthy that Dr Lane Claypon dismisses practically all biological influences, so that enzymes or ferments are ruled out as playing any possible rôle in nutrition. These conclusions do not on their face appear to harmonise with modern work on the subject of nutrition, nor do they quite fit in with the view that ferments or enzymes are essential as activators in the great nutritive processes. Recent observations tend to show that a chemically ideal or physiologically balanced diet does not necessarily nourish its consumer unless there are present certain substances, while it is difficult to believe to take a familiar example, that a hard-boiled egg, with its albumin stiffly coagulated, can be dietetically as serviceable as a raw or lightly cooked egg. Too much stress, however, cannot be laid on this argument, as one of the first stages in the natural digestion of milk is the coagulation of the caseinogen. But research has in fact shown, as we should expect, that from an absorption point of view all is in favour of the raw egg, while boiled milk means that multiple changes take place not only in regard to the albumin of the fluid, but also to its other constituents. Boiling as a safeguard against bacterial infection is, of course, sound enough, but it cannot be that milk so treated is chemically, physiologically, or physically the same as the milk direct from the breast. Yet, in spite of these considerations, the evidence of practical experience appears to show that certainly in a large number of cases milk does not lose any of its nutritive value by boiling. Dr Lane Claypon shows that some children thrive better on raw milk, others on boiled milk, and therefore we must conclude that individuality is a grand factor in the situation.

THE INFLUENCE OF SPINAL ANÆSTHESIA ON BLOOD PRESSURE

SPINAL anæsthesia is not so generally adopted as perhaps it deserves to be owing to the variable and contradictory results obtained, some surgeons having, after repeated trials, abandoned the method. In order to ascertain whether spinal anæsthesia has any undesirable effect on the blood pressure in comparison with general anæsthesia by ether and chloroform, Dr Pietro Amaglio made a series of observations which are recorded in *Il Morgagni* (Part 1, No 5, May 31st, 1916). The anæsthetic used was a 5 to 10 per cent solution of novocaine, and observations were made with a Riva Rocci sphygmomanometer on 37 cases. It was found that the arterial pressure was sensibly affected in 16 of the cases, in some slightly, not exceeding a diminution of 5 mm and of small duration, returning to normal towards the

¹ Milk and its Hygienic Relations. By Janet E. Lane-Claypon M.D. D.S. Lond. Published under the direction of the Medical Research Committee (National Health Insurance). London: Longmans Green & Co. 1916. Pp. 3. Price 7s 6d net.

end of the operation with the gradual return of sensation, in others the effect was more decided and persistent, a diminution of 15-20 mm requiring injections of infundibulin and camphor to restore it. The maximum observed was a diminution of 45 mm. In the remaining 21 cases there was no appreciable effect on the arterial blood pressure. These results are somewhat different from those of Solaro and Borghi, who recorded a rapid and constant lowering of blood pressure of 10-50 mm. These observers, however, used a mixture of stovaine and novocaine. From a general point of view, therefore, it may be accepted that spinal anaesthesia by novocaine alone has little influence on the arterial pressure, and that in those cases in which it is affected the lowering is usually transitory, and that when it is persistent the administration of the usual remedies will restore it to normal in a short time, varying from a few hours to a maximum of 24. Dr Amaglio considers that spinal anaesthesia by novocaine merits a more extensive practical application in view of the researches of Dalt and Pozzilli on the influence of ether and chloroform narcosis on the blood pressure, which was decided. For whereas in ether narcosis there is a preliminary period of a marked rise in arterial pressure which then returns slowly to normal, chloroform narcosis, on the other hand, produces from the commencement a noticeable lowering, which is sometimes restored after a longer or shorter time, but which at other times persists or becomes so accentuated as to threaten life. Ether being in this respect preferable to chloroform, by comparison spinal anaesthesia having very slight influence on the blood pressure should be logically preferable to either.

THE CARNEGIE UNITED KINGDOM TRUST AND INFANT AND MATERNAL WELFARE

WE understand that the Carnegie United Kingdom Trust, desirous of obtaining a comprehensive report upon the provision made throughout the country for promoting the physical welfare of mothers and infants, have prepared a schedule containing a large number of questions indicating the scope of the inquiry and the aspects of the subject upon which information is sought. Copies of this schedule have been sent to the medical officers of health of the larger sanitary districts, together with a copy of a letter signed by Dr E W Hope, the medical officer of health of Liverpool, requesting that the required information should be sent to him in order that the Carnegie trustees "may be in a position to decide what steps of a practical nature can be taken by them (if any), and generally to assist in the solution of the problems in question." The schedule, which covers the ground in a fairly comprehensive manner, is divided into seven sections. Section A contains inquiries into the general sanitary condition of the district. Section B concerns itself with the activities of local authorities with special reference to infant and maternal welfare. While Section C requires similar information in respect to the activities of voluntary agencies. Section D is devoted to the Poor law aspect of the question, Section E to information connected with midwives. Section F to education in mothercraft, and under Section G space is provided for general observations by the medical officer of health of the district. It is satisfactory to know that the Carnegie trustees are taking a practical interest in the very important

subject of infant and maternal welfare, and that they have apparently placed the matter in the hands of Dr Hope in order that he may draw up a report on the matter, but we must, at the same time, express surprise at the manner of conducting the inquiry. We should have thought that all the required information would have been in the possession of the Local Government Board, and that it might have been obtained from them direct without troubling medical officers of health to fill up special inquiry forms for the Carnegie trustees giving information which these officers have doubtless already supplied to the central public health authority. Medical officers of health have nowadays a very large number of official returns to fill up—some think far too many—and, at the present time, when most of them are short of staff owing to the exigencies of war, it is rather surprising that this additional and, as it seems to us, unnecessary, burden is sought to be placed upon them. Dr Hope's letter to the medical officers of health of the districts to which the schedule of inquiry has been sent is vague as to the use to which the Carnegie trustees intend to put the information on infant and maternal welfare once they have got it, and it is unfortunate that he was not a little more explicit on the point. This branch of public health work is at present under the control of two Government departments—i.e., the Local Government Board and Board of Education—both of which are empowered to make grants of public money to assist in financing local schemes. It is to be hoped that the Carnegie trustees do not intend to make an already complicated position more complicated, the proverb of too many cooks spoiling the broth is none the less true because it is true, and it would be sad if it became applicable to the activities of those who have at heart the welfare of mothers and children in this country.

EMPHYEMA AFTER PNEUMONIA

PNEUMONIA is without doubt the commonest cause of empyema. Empyema is no less one of the commonest sequels of pneumonia. Dr G Nilson¹ has met with 32 cases of empyema among 465 patients treated for pneumonia at the Karlskrona Seamen's Hospital between the years 1903 and 1915, and discusses the treatment of the condition. Borelius, describing in 1914 34 cases of metapneumonic empyema met with at Lund found that 12 recovered after a single thoracocentesis and withdrawal of the pleural exudate, while 5 more recovered after repeated pleural puncture the remaining 17 required operation, the removal of a piece of a rib. The average durations of these treatments were 37 days 107 days and 52 days respectively, and Borelius came to the conclusion that primary thoracotomy, the resection of a piece of a rib, should therefore be regarded as the normal treatment of such empyemas. In describing his own experience Dr Nilson remarks that certain years, such as 1903 1909, and 1915, impress themselves as "pneumonia years" in the personnel of the navy, and also as "empyema years." During such years the cases of pneumonia averaged 60 instead of the usual 35 and the percentage developing empyema rose from the average 7 per cent to 11 per cent. The empyema declares itself four or five weeks on the average after the beginning of the pneumonia. The three earliest

¹ Nordisk med. Arkiv. Stockholm. 1915. Vol. I. Hefte 2.

cases occurred 8, 9, and 11 days respectively after the onset. Borelius lost 7 out of his 34 cases of empyema, Dr Nilson lost 3 out of his 32, 1 from spread of pneumonia to the other lung, 1 from multiple arthritis and heart failure, and 1 died suddenly during apparent convalescence two months after the operation, death being due to embolism of the pulmonary artery by a clot from the left hypogastric vein. In operating for empyema, Dr Nilson resects four or five inches of rib, and clears out any collections of fibrin he may be able to reach in the cavity. Recovery, he finds, takes place in 13 weeks, on the average, but is more rapid in the cases with small collections of pus, and slower in those with large collections. Thus in 3 of his 32 patients the amount of pus in the pleural cavity was less than one litre, one patient died, the other two recovered in 7 or 8 weeks. In 18 cases the pus amounted to between one and two litres, the average duration of the post-operative treatment was 12 weeks. In 9 instances the quantity of the pus was between two and three and a half litres, and the after treatment averaged 16 weeks in length. One patient yielded four and a half litres of pus, and was still under treatment 19 weeks later, one patient yielded seven litres, or 12 pints, of pus, and recovered in 24 weeks. Dr Nilson's patients were mostly young men aged between 20 and 28, he remarks that 3 died, 2 were still under treatment when he wrote, and that the remaining 27 made good recoveries and did not require any thoracoplastic operations for failure of the lung to expand. He concludes that his figures prove the advisability of treating meta-pneumonic empyema in adults by primary resection of a rib, while thoracocentesis may prove satisfactory in the cases of children with small empyemas after pneumonia or with pleural exudates that are almost serous in character.

THE INSUFFLATION OF SULPHUR IN THROAT AFFECTIONS

BLOWING flowers of sulphur on to a throat exudation was probably a not unusual remedy among medical men in the past, although on the authority of Professor C. G. Bäumlér¹ it was first recommended by Legauterre in 1866. The proceeding seems to have fallen into disrepute in the metropolis about the time when the first hospitals of the Asylums Board were being opened in the 'seventies.' Sulphur although attacked by living protoplasm, is probably quite unaltered by a mucous membrane—Brace and Dilling state categorically that it remains unaltered in the stomach—and the application partook more of the nature of a rite than of serious treatment, it was akin to placing a stick of solid sulphur in a dog's drinking water which was at one time supposed to protect the animal from eczema. Doubtless the insufflation of sulphur persisted longer outside London and as a popular remedy. A letter in *THE LANCET* of Jan 26th, 1895, compares the efficacy of sulphur and antitoxin in the treatment of diphtheria, concluding in favour of the former and the following issue contained a statement by another correspondent to the effect that sulphur is a most excellent remedy in all ulcerative throat affections. Quite recently Sir William Whitt states in the latest edition of his 'Elements of Pharmacy' 'Sulphur is a popular

local application to the false membrane in diphtheria, either as a gargle or insufflation." It is therefore not altogether surprising to have a tragic reminder of its possible evil consequences in the report of a recent inquest at Newport (Mon) at which medical evidence was given to show that the death of a girl of 9 years was due to asphyxia caused by the presence in the larynx of flowers of sulphur which had been blown there by the girl's mother who had heard of it as a remedy for diphtheria. Dr Rees Morgan, who made the post-mortem examination, informs us that the practice in question is still quite common in South Wales and Monmouthshire. Some sulphur is shaken on a sheet of paper, which is then rolled up into a tube, one end of which is placed as far as possible down the patient's throat while the operator blows into the other end. Now that publicity has been given to the danger of the practice as well as to its uselessness, it will, we hope, die out altogether.

THE METROPOLITAN WATER-SUPPLY

MARCH, like February, was on the whole a wet month, the mean rainfall at 12 stations which have been selected as giving equal representation for all parts of the Thames basin being 4.58 inches, which is 2.47 inches above the average mean rainfall for this month during the previous 33 years. The result was a deterioration of the raw river waters, as judged by the albuminoid nitrogen, per manganate, turbidity, and colour tests. Similarly, the filtered waters showed some falling off or showed no change by chemical tests or in regard to colour. The filtered waters, however, generally speaking, showed a high standard, and whereas 100.0, 100.0, and 34.8 per cent of the samples of raw Thames, Lee, and New River water respectively contained typical B coli in one cubic centimetre (or less) of water 81.7, 69.6, and 65.5 per cent of the filtered water samples derived from the Thames, Lee, and New River respectively contained no typical B coli even in 100 times as much water—namely, 100 cubic centimetres. The efficiency of the storage and filtration processes is thus again made evident and the metropolis enjoys an immunity from water borne disease.

HERPES ZOSTER AND VARICELLA

In the *British Journal of Dermatology* for January-March of this year is an article by Dr F. Parkes Weber on two cases of herpes zoster associated with a generalised eruption of varicella like spots. From the precis of the literature given by Dr Parkes Weber it can be gathered that such cases are not infrequent and constitute a group of considerable interest and not a little obscurity. The first case is that of a male aged 59, suffering from chronic lymphatic leukaemia, who after a fortnight's treatment with arsacetin developed an eruption of typical herpes zoster over the right shoulder. Five days later a generalised but scanty eruption of varicella like spots appeared, they were scattered about the trunk and gradually disappeared without causing any trouble, whereas the zoster was followed by depressed scars covered with dark scabs. The second case was a woman aged 60, who developed typical herpes zoster in the distribution of the left trigeminal nerve. The attack was severe, the herpes soon becoming confluent and partly hæmorrhagic, with much œdema of the whole face. The preauricular glands and those along the anterior border of the sternomastoid were very

¹ On the Use of Sublimed Sulphur as a Local Application in Diphtheria, *Brit. Med. Jour.* March 2nd 1904 p. 420.

enlarged and tender. After a week a generalised vesicular eruption like varicella, very scattered, appeared over the trunk and extremities. It vanished gradually after some two weeks, but the herpes did not disappear completely till some two months had elapsed. In some of the recorded instances the so called varicella has preceded the outbreak of the herpes zoster, in others the two have been practically synchronous, while in others still the varicella has been subsequent to the herpes, as in Dr Parkes Weber's cases. Were it merely a question of the two conditions occurring thus together or in close relation to each other, the problem would be less baffling than it will be seen to become when the following additional facts are borne in mind. In some cases reported by Bokay at the International Medical Congress of 1909 (Budapest) one child in a family developed typical varicella ten days after an eruption of herpes zoster in another child in the same family. A considerable number of such cases have been put on record zoster following varicella in different members of the same family or varicella following zoster. Further, in some cases of apparently ordinary varicella the rash shows local zoster like grouping of the vesicles, which may be associated with pain. Various hypotheses have been put forward to account for these curious phenomena. It has been suggested, to begin with, that herpes zoster and varicella are due to identically the same cause or morbid agent, some as yet unrecognised virus or organism. If this were so, as Dr Parkes Weber remarks, we should expect to find frequent cases of herpes in varicella epidemics. As a matter of clinical fact this association is not found. Nor is the association of herpes and varicella in the same individual noted as an occurrence in epidemics of the latter. Again, in many cases of herpes of the symptomatic variety it seems possible to exclude the action of any varicella virus, in the sense that the herpes is adequately accounted for otherwise. Heim has suggested that the unknown microbe of varicella may under certain as yet obscure conditions give rise to a localised eruption resembling herpes zoster, and that this again may further give rise to a varicella like rash. There is, it may be remarked, no *a priori* reason why true herpes zoster and true varicella should not occur more or less simultaneously in the same individual, some, at least, of the reported instances might thus be explained. It should be borne in mind, also, that histological evidence shows that the spinal manifestations of herpes zoster, while in part definitely localised, are also diffuse, and it is therefore quite conceivable that in certain cases the rare and scattered varicella like vesicles accompanying an attack of zoster are due to diffusion of the herpetic virus in the nervous system. In this connexion the analogy of acute poliomyelitis is instructive, the manifestations of the virus of that disease are diffuse, although it is undoubtedly massed in the ventral cornua. Sometimes the virus of poliomyelitis "overflows" and sensory phenomena result, sometimes the postulated virus of herpes overflows and motor phenomena result. Perhaps the chief difficulty in the whole question of the possible relation of herpes zoster and varicella is one of interpretation. Thus one observer in a case of herpes with generalised eruption said that the eruption "looked like" a bad attack of varicella. There is the problem. A typical case of herpes zoster and a classical case of varicella is thus diagnostic hesitation, but when varicella is clustered, and when herpes is diffused or scattered

difficulties arise. On the margins of the affected segmental cutaneous area or areas in herpes the clinician will not infrequently find more or less isolated vesicles, but these do not embarrass him because of the massing of the rest of the eruption. A consideration of the interesting data which Dr Parkes Weber has collected serves to accentuate the feeling that light will be thrown on not a few of the hitherto insufficiently studied exanthemata by research along the lines of their serology and the condition of the cerebro spinal fluid in such cases and that the occasional nervous symptoms and accompaniments of the exanthemata are of greater significance than their rarity leads the observer to suppose.

ANNUAL REPORT FOR 1914 OF THE REGISTRAR-GENERAL

BY JOHN F W TATHAM, M A, M D D U R
F R C P L O N D & I R E L, D P H, & C,
LATE SUPERINTENDENT OF STATISTICS GENERAL REGISTER OFFICE

II

Standardised Death rates

In the reports of the Registrar General issued since the last Census the term "standard death rate" has been substituted for the term "corrected death rate" previously employed in this country. This change has been made at the suggestion of Dr Cressy Wilbur, chief statistician to the American Census Bureau, who applied it in the compilation of the Census Bulletins for 1911. In that document reasons are given for the adoption by the Bureau of the population of England and Wales in 1901 as the standard of correction for the death rates. Dr Stevenson's arguments in favour of this substitution will be found in the official report for the Census year.

In a condensed table in the report for 1914 both the crude and the standardised death rates are stated without reference to age or cause in each of the four groups of geographical areas employed in these reports. The rates are also given for the preceding year and for the quinquennium 1906-10. In another table the mortalities are shown of the various sex and age groups from which the standardised rates are calculated and a third table compares the mortality by sex and age in the various classes of area with that of England and Wales generally.

As the constitution of the English population in 1914 was less favourable to low mortality than in 1901 standardisation of the death rates on the basis of the latter year slightly reduces the rate of the whole country. The effect upon London and the smaller urban districts is insignificant but the mortality of the county boroughs is increased by 3 per cent, whilst that of the rural districts is diminished by 15 per cent, the contrast between them being thus materially increased. Outside the metropolis mortality increases generally with urbanisation but the mortality of London is intermediate between that of the county boroughs and that of the smaller urban districts and in the case of females is even lower than that of the urban districts as a whole. This is equally true of the four years 1911-14. As in the three preceding years, the proportional as well as the actual excess of male mortality was least in the rural districts and increased with urbanisation to a maximum in London. The evidence is therefore consistent that urban conditions tell more severely on males than on females.

In a further table comparison is made of the mortality experienced in the North, the Midlands and the South of England and in Wales with distinction of sex and class of area. It shows as did similar tables for the three preceding years that the standardised death rates of the north at all ages considerably exceed those of other parts of England. Mortality in Wales falls as a rule between that of the north and that of the remainder of the country.

The detailed abstracts for 1914 which bulk largely in this volume show the causes of death of males and females in 27 groups of ages for the whole of England and Wales.

several geographical divisions. The tables in this report are arranged according to the short list of causes adopted by the Registrar General and the Local Government Board. These tables are identical in form with the Board's Table III, and are common to the reports of both authorities.

Classification of Causes of Death

For many years past attempts have been made in the General Register Office to improve the classification of causes of death. Inquiries still continue to be addressed to medical practitioners with the object of eliciting fuller information respecting deaths the causes of which are unsatisfactorily stated in the certificates.

Since 1911 similar inquiries have been made to coroners. As many indefinite certificates are received regarding deaths that have been investigated by coroners' juries, it has been decided to ascertain whether definite information not embodied in the verdict might be obtained from the medical evidence at the inquest. Thanks to the courtesy of coroners, this has been proved to have been so in many instances—deaths certified as due to syncope, natural causes, &c., having been referred in the records to official headings on the strength of excerpts furnished from the medical evidence. Many years ago similar attempts were made to obtain this information but for reasons which have not been stated those attempts were unsuccessful.

In order at once to facilitate inquiries and if possible to diminish their number in future, a list of indefinite forms of certificate, with indications of the further information desirable in each case, is distributed with the inquiries and is bound up with the books of death certificate forms officially issued. By this means the supplemental information desired in any given case is readily indicated, moreover it has been found that the number of deaths imperfectly certified has fallen appreciably since the list came into use. Referring to this topic in a recent report Dr Stevenson quotes a number of instances in which the issue of these inquiries renders it possible to ascertain the meaning attached by practitioners to their use of various conveniently indefinite terms. He observes that these are questions in regard to which no assistance can be expected from nomenclatures or from text-books, for it is the function of these to discourage, not to define the use of such expressions. And even if the meaning rightly attaching to such terms could be laid down by authority, this would not necessarily supply the answer to the question which the tabulator must ask himself—viz.

What does this expression mean to the man who has used it? This question can only be answered by reply to inquiry directed to the user himself.

Several instances are related of improvement in classification resulting from these inquiries. Thus in many cases originally attributed to tuberculosis the deaths are ultimately classed as due to the pulmonary form of that disease, whilst in other cases indefinitely referred to rheumatism the classification eventually reached is "rheumatic fever." Further instances of improvement are indicated in the following statement of deaths registered in 1914—

Originally Certified	Finally Classified
253 from cereb. sp. men. or basal meningitis	116 to cereb. sp. fev., 51 to tubercular meningitis
203 from fibroid phthisis	121 to pulmonary tuberculosis
376 from cerebral tumour	13 to tub. men., 23 to syphilis, 35 to cancer
897 from cancer (indefinite)	In 809 cases to part or organ affected
376 from peritonitis	21 to tub. perito., 67 to appendicitis
295 from syncope, heart failure	122 to definite heart disease
150 from other indefinite causes	In 952 cases classification has been improved

By this system, which has been in operation for many years, the accuracy of the returns of causes of death is being constantly improved, and as the Registrar General is dependent in regard thereto upon the goodwill of medical practitioners, Dr Stevenson very properly acknowledges the services thus willingly rendered.

Enteric Fever

The loss of life from this disease has been less since the last Census than in any previous period on record. The death rate in 1914 was 45 per 1,000,000. In no year before 1905 was the rate so low, and less than twice its present amount.

From a public health view point the significant fall in enteric fever mortality will naturally be claimed as proof of the efficiency of modern sanitation. But the fall has been so remarkable as to suggest resort to further investigation. The vast experience of the Metropolitan Asylums Board goes to show that amongst the admissions for enteric fever there are a very large proportion of cases which are not really examples of that disease. Again evidence has recently been adduced of the existence of considerable alteration of fashion as regards the nomenclature of typhoid like diseases. These considerations should have weight in relation to the present matter.

The three counties with highest enteric fever mortality in 1914 were Durham, the West Riding of Yorkshire, and Northumberland, and the three county boroughs were Devonport, Wigan, and Hull. Durham the county of highest mortality in 1914, was fifth highest in 1912 and 1913, while Devonport the county borough of highest mortality in 1914, was second in the previous year and first in 1912. These figures confirm the conclusion drawn on previous occasions that the maintenance of enteric fever mortality at its present level is largely due to the relatively backward position of a small number of areas.

Scarlet Fever

The deaths from this disease in 1914 were equal to a rate of 77 per 1,000,000 at all ages and of 229 per 1,000,000 at ages under 15 years. Very remarkable is the decline in mortality from this disease which has taken place during the last half-century. Until 1895 no year experienced a mortality less than double that of the year under notice. Viewed from the standpoint of the deaths alone it might be thought that the disease was tending to disappear entirely. But the notification returns prove that it is still widely prevalent, the diminished mortality corresponding to mildness of type of the disease which contrasts sharply with the type prevailing a generation ago.

The towns yielding the highest death-rates from scarlet fever were Preston, Oldham, Salford, Warrington, and Middlesbrough, and of these Preston, Warrington and Middlesbrough have returned rates above the average for county boroughs in each of the last three years. This tendency to persistently higher mortality year after year in the same locality is similar to what obtains in the case of enteric fever, and contrasts strongly with the behaviour of measles and whooping-cough which seldom furnish high rates of mortality for three consecutive years in the same district. The explanation doubtless lies in the fact that the proportion of children attacked by scarlet fever is much below the proportion for measles and whooping-cough, so that after even a severe outbreak the majority would generally be unprotected by a previous attack. This applies still more to enteric fever, whereas a severe outbreak of measles or of whooping-cough limits itself by almost exhausting the supply of susceptible children.

The fatality of this disease is not given in the present report, but in the year 1912 it amounted to 19 per 1000 cases reported. The fatality in London where 94 per cent of all the deaths occurred in hospitals may be compared with the experience of the Metropolitan Asylums Board. During 1912 the fatality in the Board's hospitals was 1.6 per cent of the cases treated as against 1.5 per cent among notified cases treated at home. The ratio of hospital deaths per cent of admissions has gradually fallen from 13.1 in 1876-80 to 2.7 per cent in 1906-10. The type of disease in London was mild in 1912 even beyond the average of recent years.

Diphtheria and Croup

The deaths thus returned in 1914 correspond to a rate of 160 per 1,000,000 at all ages—the mortality at ages under 15 being equal to 501 per 1,000,000 at those ages. Very decided is the effect of standardisation upon the death rate at all ages. All the crude diphtheria rates require increase to render them fairly comparable with those of 1901 on account of the diminished proportion of children now living. Middlesbrough, Great Yarmouth, Northampton, Devonport and Portsmouth were the towns of highest mortality the last three of them having exceeded the average for each of the last four years. The fatality of diphtheria like that of most other infectious diseases of early life decreases rapidly with age. In the experience of the Metropolitan Asylums Board during the Census year it decreased from 342 per 1000 admissions under 1 year of age to 22 per 1000 at ages

10-15 The ages at which attack occurs therefore largely influences the fatality. In the year 1911 nearly half the deaths from diphtheria and group occurred in public hospitals.

Tuberculosis

The general death rate from tuberculous affections in the aggregate was 1361 per 1,000,000 living, which is less than that of any previous year except 1913. The deaths from that disease were equal to 9.7 per cent of the total deaths. The death rate has fallen to this figure notwithstanding a change in the constitution of the population which favours tuberculous mortality. Compared with the average rate for 1906-10 the standardised mortality in 1914 shows a reduction of nearly 14 per cent. For the population generally and for the male sex tuberculous mortality varied in the same way with urbanisation, from a maximum in London to a minimum in the rural districts, but a higher mortality for women was recorded in the county boroughs than in London. The excess of female mortality in the county boroughs over that in the rural districts was 39 per cent, but for males the excess of the London rate over that of the rural districts was 114 per cent. It is therefore evident that urban conditions of life increase the risk of tubercle much more for males than for females.

A PORTABLE FRACTURE BOX

FOR USE IN FIELD AMBULANCES AND FIELD HOSPITALS

By ST J DUDLEY BUXTON, M R O S, L R O P, B S LOND,
CAPTAIN R.A.M.C.

THE field fracture box in the equipment of each section of a field ambulance has been proved by experience to be out of date. Its contents have been found unsuitable for the treatment of fractures due to gunshot wounds, plaster of Paris, now little used in field hospitals, adds considerably to the box's total weight of 82 lb. It has been customary of late to send up to units large numbers of additional splints, and when field units are stationary this system has not many disadvantages. However, in some fighting areas it is necessary for all equipment to be carried on mules, and for these reasons I have collected and put together such splints as I consider most practical in the treatment of gunshot wounds involving bones, so that they can be carried by mule transport.

Major E. B. Waggett, R.A.M.O. (T.F.), recently made a fracture box which weighed about 60 lb. It was suited for those who worked with him, but did not contain several simple appliances which others would look for in a fracture box. The box I am about to describe is much heavier (90 lb.) but the weight could at any time be lessened by throwing aside articles which some might consider dispensable under the circumstances in which they were placed. This weight is of no disadvantage if the fracture box is conveyed in the medical store cart, and when carried on a mule it can be counterbalanced by the medical comfort pannier, carried also in the medical store cart. Such a weight of 180 lb. in addition to pack saddlery is not the greatest weight some of the pack mules are able to carry.

The box was made and fitted in the field ambulance and all splinting and contents are such as can be obtained from a depot of medical stores. The box itself measures 22 by 12 inches, and is 16 inches deep, these are inside measurements. It is made of $\frac{3}{4}$ inch wood with the ends of $\frac{7}{8}$ inch wood, it is strengthened by iron girders where the ends and sides are joined, and by wood girders (3 inches broad) $2\frac{1}{2}$ inches from each end. To each wood girder is screwed a 1 inch leather strap and buckle 7 feet 6 inches long. This completely encircles the box but is not fixed to the lid, and allows loose splints to be fixed on to the lid. Metal rings are attached to the leather for mule transport. A strong handle of thick canvas carpet binding is fastened on each end of the box, to allow of hand carriage.

The lid fits tightly but can be removed quickly by canvas loops tacked to it inside which protrude when the lid is in position.

On the inside of the lid (see figure) the following are attached: 1. An inch rule is painted. 2. Bag of tools containing shears (5 inch), saw and cutting pliers (as supplied in field fracture box for aluminium work), hammer and nails. 3. Six iron interruptions (7 inch) for long Liston splint

and screws. 4. Metal slot for bending aluminium strips as in field fracture box. 5. List of contents of box.

Contents of box (see figure)—Tow, 4 lb., triangular bandages 150, straps and buckles, 60, tape, 2 packets, sand bags (20 inches long), 30, safety pin boxes, 3, old sheet, rubber adhesive plaster (7 inch) tins, 3, (2 inch) rolls, 2.

Splinting material—Aluminium strips, 60-inch lengths 4, 18-inch lengths 5, aluminium ribbon rolls, 3, Gooch splinting, roll, 1, assorted, bag, 1, vulcanite fibre, sheets, 3, pasteboard, bag, 1.

Showing the fracture box open and the inside of the lid. a Back splint b Thomas's splint c aluminium strips d plaster adhesive e iron interruptions for Liston's splints shown on each side f tool case g Liston's splints h metal slot for aluminium work i list of contents

Splints.—Arm. Angular arm (for internal or external) wood, 4 (N.B.—These splints can also be used for side splints for leg and foot, one arm being longer than the other), angular arm, wire 3 straight, wire 4, wrist for dorsal flexion of wrist and hyperextension of fingers, iron, 1 Carr's splint, 2.

Leg. Thomas's knee splint 3, long Liston's splint 8 Cline's splint 4 pairs. Back splint and foot piece 3.

* These splints are too long to go within the box and are fixed beneath the encircling straps.

The difficulty of carrying a number of Thomas's knee splints is known by everyone, and this is augmented by a supply of heavy ones. There are three with this fracture box but more could be carried if light ones were obtainable. Some supplied weigh $7\frac{1}{2}$ lb. but this is excessive. In places the A.O.D. have made these splints weighing only 2 $\frac{1}{2}$ lb. and of this kind more can be carried. The long Liston cannot be dispensed with owing to this difficulty of carrying Thomas's splints and it is made of wood useful for the manufacture of other shorter splints. Only 4 lb. of tow are included since plenty is carried in a G.S. pannier. For the same reason the number of carpentering tools is limited since screwdriver, saw &c. are contained in a G.S. pannier.

My thanks are due to Captain G. W. Harris for the photograph from which the figure is reproduced.

PRESENTATION TO A MEDICAL OFFICER.—Captain Alexander Findlater R.A.M.C. (T), medical officer of the Hendon Union has been presented by the residents in the Hendon Union and the district with a purse and an illuminated address in recognition of his having won the D.S.O. for conspicuous gallantry while serving in Gallipoli.

ORDER OF THE EXCELLENT CROIX.—Dr. J. B. Watson has been granted His Majesty's Royal Warrant to wear the Order of the Excellent Croix of the Sixth Class conferred upon him by the late President of the Republic of China in recognition of valuable services rendered.

SCOTLAND

(FROM OUR OWN CORRESPONDENTS)

Scottish Midwives' Association Formed

At a representative meeting of Scottish midwives held in Edinburgh last week, Dr Laura Stewart Sandeman presiding, it was unanimously approved that an association should be formed called "Scottish Midwives Association," and a committee was appointed to make the initial arrangements.

The Edinburgh Medical Guild

The Edinburgh Medical Guild has recently sent to the press for publication the following résumé of the objects which it exists to provide: (1) The same free choice of doctor for the insured person as in private practice, (2) freedom from any contract other than the moral obligation of the doctor to his private patient, (3) the same supply and quality of medicines for insured as for private patients, and (4) protection against the abuse which can be made of the corresponding provisions under the present Acts, consisting in wholesale "contracting out" and the formation of medical aid institutes.

A Catgut Industry in Edinburgh

A factory has been established in Edinburgh for the manufacture of surgical catgut ligatures. The catgut used in this country prior to August 1914 came from Germany and since that date American gut has largely taken its place. The reports as to the quality of the Edinburgh product are encouraging. A number of leading Edinburgh surgeons have used it with satisfactory results in the wards of the Royal Infirmary and it is also being supplied to the London and other hospitals. The manufacturer states that after extended experiments he has found it impossible to produce from catgut obtained under septic conditions a sterile ligature by means of subsequent medication after the strings have been twisted and dried without to some extent altering the character of the gut and impairing its tensile strength. The strength of the chemical solutions which require to be used and the length of time it is necessary to allow the catgut to remain in contact with them cannot be otherwise than detrimental to the ligature. Much of the trouble experienced through irritation in the suture and on account of lack of uniformity of absorption has he considers been due to this non scientific method of preparation of medical ligatures. The sterile ligatures are manufactured in Edinburgh from the raw intestines selected from freshly killed animals to the finished article ready for immediate surgical use. The director of the Royal College of Physicians' laboratory has made a favourable bacteriological report upon it.

Dundee Royal Infirmary Annual Report

The annual meeting of the directors of the Dundee Royal Infirmary was held on June 13th, when the yearly report was submitted. During the year up to May 15th 4030 patients were admitted to the wards, this with 323 patients remaining from the previous year brought the total of patients treated to 4352, an increase of 42 on the previous year. In the maternity department 303 were treated in the wards and 532 at their own homes. The cost per occupied bed was £70 19s 1d compared with £69 19s 7d for last year.

June 25th

IRELAND

(FROM OUR OWN CORRESPONDENTS)

Irish Medical Association Annual General Meeting

The annual general meeting of the Irish Medical Association was held on June 21st in the Royal College of Physicians. Dr F. W. Kidd, the outgoing President, presided at the opening and the chair was subsequently taken by the new President Mr P. Marlar Blake. Mr Kidd's address on the localities maintained by the Irish medical profession during the past year referred to the new constitution of the association on which a central body had been organised in size and rendered more efficient. During the year the proposed struggle with the Insurance Commissioners on the question of certification had been fought with the success on the profession of the day for which I had contended—that each medical

man should certify for his own patient. There were still many evils to be redressed in the conditions of the Poor-law medical service. Up to the present a dispensary medical officer could be awarded a pension only as a favour and not as a right. He quoted the recent case of Mr Kelly, of Enniscorthy, who after 33 years' faithful service, was granted a pension of £100, promptly reduced by the board of guardians to £50 a year. In spite of such prospects posts in the Poor-law medical service were eagerly sought for and while there was competition guardians would continue to think it unnecessary to redress grievances. The whole question of Poor-law reform must soon receive the attention of the legislature. A Poor-law and National Insurance committee was appointed on the understanding that its activities should not in any way trespass on the functions of the Irish Medical Committee. Resolutions were carried: (1) asking the council to consider the question of Poor-law reform in relation to its medical service so as to be able to formulate the views of the profession when the contemplated legislation on this subject is introduced, and (2) recommending that the principles of the Midwives Acts (England and Scotland) should be embodied in a special Act suitable for and made applicable to Ireland. A further resolution was passed directing the council to coöperate with other medical bodies in Ireland in endeavouring to promote an agreed measure. The meeting terminated with a vote of thanks to the outgoing President.

Death of Lieutenant Colonel Patrick J. Dempsey
M D R C I D L

The death is announced at his residence, Aghadowey, on June 24th, at the age of 63 of Lieutenant-Colonel P. J. Dempsey J.P. for the county of Londonderry. A native of the Aghadowey district, he studied at the Catholic University School of Medicine, Dublin, and at Queen's College, Belfast, graduating M.D. of the Royal University in 1876. He afterwards obtained a commission in the Royal Army Medical Corps and served for 30 years in India, and also for two years with the Turkish army. While in India he was associated with many reforms in hospital work, and in the organisation of the Royal Army Medical Corps.

UNITED STATES OF AMERICA

(FROM OUR OWN CORRESPONDENT)

The Destruction of Lice

THE best and cheapest way to get men free of lice with the least possible interference with their military duties is to dust them all over with naphthalin after a preliminary cleaning—if we accept the teaching of (Surgeon General) Medical Director H. G. Beyer, of the United States Navy, who had been working in the Naval Hospital at Hamburg with the German Red Cross. Each man's clothes he says are disinfected by steam at low pressure (103°C) for 40 minutes while he has his hair cut off and is given a bath with hot water and soft soap. At bed time he wears all his clothes and finely powdered naphthalin is introduced down his neck between his underclothes and skin. During his sleep this evaporates and kills the lice, of which always a few survive the cleaning. This process is repeated on each of the two following nights and the man is thus cleared of the pest at a cost for naphthalin of 3ths of a penny merely. These disinfections have had to be done in Germany on a great scale, one is mentioned in a camp of 25 000 Russian prisoners, in another camp of Russians it was as we know that von Prowazek contracted the typhus fever of which he died.

The United States and the Red Cross

The United States warmed by the experience of Europe is preparing her Red Cross services as I have before mentioned. Ten Red Cross base hospitals are organising to help the army and are being formed in relation with the large civil hospitals which will each of them probably furnish a whole hospital or a section accustomed to work together with doctors male and female nurses, clerks, cooks, etc. and voluntary aid ladies as nurses and transport sections will be organised probably in relation to the Universities. Five small hospitals are to be prepared on the Atlantic coast as auxiliaries to the navy it is announced by the Secretary of the Navy Mr Daniels who is good

enough to take a great interest in the Naval Medical Department. He recently told a class of newly joined surgeons that the preparedness of a ship lies just as much in the medical administration as in the administration on the bridge—a novel proposition indeed, still, it cannot but have sent them to their life's work with enthusiasm.

An Act to Himself

Either the regular position of an individual medical man is a matter of grave importance to the State, or the maxim "De minimis non curat lex" can scarcely be held to apply in the United States. J B enlisted in the United States navy as a bluejacket at the age of 26, and served on for 12 years. Leaving that service, he went to college to study medicine and duly qualified. He has now joined the Naval Medical Department as an acting assistant surgeon, but as he is over 40 a special Act of Parliament is being passed to regularise his appointment. Many Acts have been placed on the statute books of many nations with less reason.

As Others See Us

The *Military Surgeon* for May has a letter from a United States surgeon working with the British army. He has one bitter complaint, and some thorough going Englishmen may find it justifiable. In the United States he was accustomed to steam-heated rooms and he feels very uncomfortable under European conditions. "I have not been warm," he says, "since I left the steamer, there is no way to heat these houses, and the English are so fond of this rotten bone seeking cold, that if the little 2 by 4 fireplace is steamed up in the living room, when they enter they say, 'My word! but it is stuffy,' and open go all the doors. So I have given up trying to get warm, and am trying instead to get used to the cold."

BULLETIN OF THE NAVAL MEDICAL ASSOCIATION OF JAPAN

The November, 1915, issue of this bulletin, just received, written in the Japanese character, contains brief abstracts in English. Among the contents is an original article by Staff Surgeon B. Shimshu on Radium Treatment of Cancer of the Oesophagus, describing the author's experiments on six cases of stricture of the oesophagus caused by cancer. In five of the cases the stricture was remarkably benefited, the sixth case ended in death without showing any improvement. In the dissection of this latter case it was noticed that the cell group of epithelioma had lost their proper type, and the cancer cells were necrosed. The same author also describes his experiences of Abderhalden's dialysis test for the diagnosis of cancer and remarks that according to his experience Abderhalden's dialysis test proved very useful. Fleet Surgeon M. Yasawa records his experiences with the diathermy treatment in various diseases. Staff Surgeon S. Matsukuma deals with chronic empyema of the maxillary sinus, and Surgeon K. Imai with the application of sensitised vaccine in relation to the mixed protective vaccine of B typhoid paratyphoid A and B. The method is this: to sensitised living bacilli 0.4 per cent carbolic acid is added, the mixture being put into the incubator (37° C) for 15 hours, which completely kills the living bacilli.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

In the 95 largest English and Welsh towns with populations exceeding 50,000 persons at the last Census, 8263 births and 4195 deaths were registered during the week ended Saturday, June 24th. The annual rate of mortality in these towns which had been 12.5, 12.0 and 12.3 per 1000 in the three preceding weeks further rose in the week under notice to 12.6 per 1000 of their aggregate civil population estimated at 17,312,235 persons for the year 1915. During the first 12 weeks of the quarter just ended the mean annual death rate in these towns averaged 14.5, against 14.0 per 1000 in London. Among the several towns the death rate last week ranged from 5.1 in Aberdare 4.3 in Oxford 5.5 in Wallasey, 6.3 in Acton, and 6.9 in Northampton to 17.1 in Norwich and in South Shields 17.2 in Wakefield, 18.6 in Gateshead, 18.8 in Oldham and 23.3 in Tynemouth.

The 4195 deaths were 101 in excess of the number recorded in the previous week, and included 244 which were referred to the principal epidemic diseases against 300 and 248 in the two preceding weeks. Of these 244 deaths 77 resulted from whooping-cough, 67 from measles 45 from infantile diarrhoeal diseases, 27 from diphtheria 15 from scarlet fever and 13 from enteric fever, but no one from small pox. The annual death rate from these diseases did not exceed 0.7 per 1000 and coincided with that recorded in the previous week. The deaths attributed to whooping-cough, which had declined from 131 to 76 in the four preceding weeks, numbered 77 and included 13 in London 9 in Birmingham, 8 in Manchester and 3 each in Walthamstow, Southampton Liverpool and Warrington. The deaths referred to measles which had been 104 70 and 65 in the three preceding weeks slightly rose to 67 last week. 11 deaths occurred in Sheffield 10 in London 6 in Birmingham, and 5 each in West Ham and Liverpool. The fatal cases of diarrhoea and enteritis (among infants under 2 years) which had been 58 63 and 52 in the three preceding weeks fell to 45 and included 16 in London and 4 in Sheffield. The deaths attributed to diphtheria which had been 32 52 and 34 in the three preceding weeks further fell to 27 and included 4 each in London and Liverpool, and 2 each in Norwich Birmingham and Pres. The deaths referred to scarlet fever which had been 8 9 and 9 in the three preceding weeks rose to 15 of which 3 were registered in Manchester and 2 in Bedford. The fatal cases of enteric fever which had been 8 and 11 in the three preceding weeks rose to 15 and included 2 each in London Stoke-on Trent and Wigan.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital which had steadily declined from 1775 to 1502 in the 11 preceding weeks numbered 1503 on Saturday last. 115 new cases were admitted during the week against 116 140 and 143 in the three preceding weeks. These also contained on Saturday last 1250 cases of diphtheria 236 of whooping-cough 190 of measles and 35 of enteric fever but no one of small pox. The 1011 deaths from

all causes in London were 105 in excess of the number in the previous week, and corresponded to an annual death rate of 12.2 per 1000. The deaths referred to diseases of the respiratory system, which had been 117 130 and 137 in the three preceding weeks, further rose to 157 in the week under notice.

Of the 4195 deaths from all causes in the 95 towns, 150 resulted from violence 320 were the subject of coroners' inquests, and 1287 occurred in public institutions. The causes of 29, or 0.7 per cent, of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts in Sheffield, Bristol Bradford, Hull and in 59 other smaller towns. Of the 29 uncertified causes, 7 were registered in Birmingham, 3 in Liverpool, and 2 each in Southend-on-Sea Manchester, and Blackpool.

HEALTH OF SCOTCH TOWNS

In the 16 largest Scotch towns with an aggregate population estimated at 2,372,000 persons at the middle of this year, 1156 births and 608 deaths were registered during the week ended Saturday, June 24th. The annual rate of mortality in these towns, which had been 14.7 12.9 and 12.2 per 1000 in the three preceding weeks, rose to 13.4 per 1000 in the week under notice. During the first 12 weeks of the quarter just ended the mean annual death rate in these towns averaged 15.5, against 14.5 per 1000 in the large English towns. Among the several towns the death rate last week ranged from 4.6 in Clydebank, 7.4 in Motherwell, and 9.2 in Falkirk, to 17.1 in Arr 17.2 in Perth and 18.7 in Hamilton.

The 608 deaths from all causes were 53 in excess of the number in the previous week, and included 52 which were referred to the principal epidemic diseases, against numbers declining from 66 to 39 in the four preceding weeks. Of these 52 deaths, 19 resulted from measles, 11 from infantile diarrhoeal diseases, 9 from diphtheria, 7 from scarlet fever, 4 from whooping-cough and 2 from enteric fever, but not one from small pox. The annual death rate from these diseases was equal to 1.1, against 0.7 per 1000 in the large English towns. The deaths attributed to measles, which had been 26, 13, and 17 in the three preceding weeks, rose to 19, and included 14 in Glasgow and 2 in Clydebank. The deaths of infants (under 2 years) from diarrhoea and enteritis, which had been 7 12 and 4 in the three preceding weeks rose to 11, of which 6 occurred in Glasgow. The fatal cases of diphtheria which had been 5 6, and 5 in the three preceding weeks, rose to 9, and comprised 5 in Glasgow and 2 each in Edinburgh and Leith. The deaths attributed to scarlet fever, which had been 5 10 and 6 in the three preceding weeks, numbered 7, and included 5 in Glasgow. The deaths referred to whooping-cough, which had been 10 9 and 7 in the three preceding weeks further fell to 4, and comprised 2 each in Glasgow and Paisley. The fatal cases of enteric fever were registered in Glasgow and Greenock.

The deaths referred to diseases of the respiratory system, which had been 83, 92, and 75 in the three preceding weeks were again 75 in the week under notice and were 17 below the number in the corresponding week of last year. The deaths from violence numbered 28, against 20 and 14 in the two preceding weeks.

HEALTH OF IRISH TOWNS

In the registration area of Dublin 263 births and 125 deaths were registered during the week ended Saturday, June 24th. The annual rate of mortality, which had been 19.3 17.7, and 17.8 per 1000 in the three preceding weeks fell to 15.9 in the week under review, against 12.2 and 14.1 per 1000 in London and Glasgow respectively.

Of the 125 deaths at all ages, 15 related to infants under 1 year and 25 to persons aged 65 years and upwards. The deaths referred to the principal epidemic diseases numbered 8 and comprised 3 from measles 2 from infantile diarrhoea and 1 each from enteric fever, scarlet fever, and whooping cough.

The causes of 6 deaths were uncertified and 3 others were the subject of coroners' inquests while 59 or 47 per cent, of the total deaths occurred in public institutions.

During the same period 185 births and 103 deaths were registered in the city of Belfast. The deaths corresponded to an annual rate of 14.0 or 11.1 per 1000 less than in the previous week, and included 16 of infants under 1 year and the principal epidemic diseases numbered 11 against 9 in the previous week and comprised 4 from infantile diarrhoea, 3 from measles, 2 from whooping-cough and 1 each from enteric fever and scarlet fever. One cause of death was inquest while 32 of the total deaths occurred in public institutions.

WOMEN MEDICAL STUDENTS AT KING'S COLLEGE, LONDON

To the Editor of THE LANCET

SIR,—The question of admitting women students in the Medical Faculty at King's College, London, has recently become urgent. We are constantly receiving applications from women who desire to study medicine here, but up to the present we have only admitted a few who are studying for the first examination (biology, chemistry, and physics) and a few who are taking physiology only for the second examination. Since the amalgamation of King's College for Women with this College we have been in the anomalous position of having opened all our classes to women with the single exception of those held in the anatomy department. As we are incorporated in the University of London this is not in harmony with the principles of that University. We have been for some time perfectly willing to open the anatomy department to women, but have hesitated to take this step because the hospitals associated with our medical school had refused to take on our women students for clinical instruction. St George's Hospital has, however, made a step forward in admitting a limited number of women students to their wards, that experiment has proved such a complete success that we are hopeful that other hospitals will follow their example. The University has also brought pressure to bear upon us, and the delegacy of the College has assented to throwing open the whole of our medical department to women students next October. In the first instance, however, the number to be admitted will be limited to 20.

We are therefore now in the position to offer medical education to that number of women for the preliminary and intermediate portions of the curriculum and we have but little doubt seeing how quickly events are marching at present, that we shall be able to secure later for them the means of completing the final or clinical step of their education.

I am, Sir, yours faithfully

W D HALLIBURTON

Dean of Medical Science Faculty King's College London

June 23rd 1916

THE INFECTIOUS CONDITION OF PATIENTS DESQUAMATING AFTER SCARLET FEVER

To the Editor of THE LANCET

SIR,—In view of the opinion now so generally held that there is but little risk of infection in connexion with patients desquamating after an attack of scarlet fever so long as there is no discharge from the nose or ears, the following incident is of interest and importance.

On June 3rd Captain H was admitted into Mrs Arnold's Hospital for Officers at Roland Gardens. He had been discharged from a fever hospital in France as convalescent from scarlet fever. He was found to be desquamating very freely on both feet. He had no discharge from either nose or ears. On June 5th he was admitted to an isolation hospital. There were four other officers in the ward to which he had been admitted. On June 12th one of these officers sickened with high temperature and general malaise and on the following morning the characteristic rash of scarlet fever appeared. The officer had not left his bed for three weeks.

There can be no reasonable doubt that this patient contracted the disease from the officer admitted during the stage of desquamation.

I am Sir yours faithfully

Green street W June 25th 1916. DONALD W C HOOD

FAT HEADEDNESS

To the Editor of THE LANCET

SIR,—During the past week the two assistants in this laboratory have been called up for service. There are some 80 soldiers in the hospital and we are constantly required to examine blood, excreta, tissues, make vaccine, and so

on. But the fat-headed committees cannot be made to see the harm they are doing by taking these men from laboratory work (useful to the soldiers) and turning them into ordinary soldiers.

I gather there is no use in appealing, but I hope you will publish this.

I am Sir, yours faithfully

R G HEN

The Laboratory Westminster Hospital, June 27th, 1916

THE EFFECT OF FERRIVINE AND INTRAMINE ON SYPHILIS

To the Editor of THE LANCET

SIR,—Mr J E R McDonagh, in his letter in your issue of June 24th, asks for the chemists who do not understand his chemistry. We were thinking chiefly of the remarks made by Professor W M Bayliss, F.R.S., at the discussion on Mr McDonagh's paper on the Rationale and Practice of Chemo-therapy, which he read before the Dermatological Section of the Royal Society of Medicine on April 13th. Professor Bayliss then said *inter alia*, 'I find in the physico-chemical hypothesis much that conveys no definite meaning to me, while the statements appear to be contrary to the knowledge which we possess.'

As to the clinical part of our paper, we can only say that our cases were faithfully reported and stand on record for any comparison which may be desired of intramine and ferrivine with other existing remedies. We can assure Mr McDonagh that we really did see *Sp. pallida* in the preparations made from our cases which had been treated with intramine and ferrivine for some days. No bias on our part could have conjured them into the microscopical field, nor could it have produced the abscesses which occurred in the injection sites of our intramine cases. The cases were perfectly straightforward ones and the therapeutic effect of intramine and ferrivine on them was real.

Mr McDonagh complains that we have "rushed into print" on a small experience. Had the experience been in any way favourable such a complaint would have been justified, but it was not favourable and one cannot continue indefinitely to experiment upon patients with remedies which are founded on what Dr C H Browning at the discussion mentioned above described as "the highly speculative discussions in Mr McDonagh's communication."

If Mr McDonagh includes amongst those who are gaining from intramine and ferrivine "advantages unobtainable with any other existing remedies" a patient whom he showed at a recent meeting of the Dermatological Section of the Royal Society of Medicine, it is good evidence that his clinical observation is not unbiassed by bias. This was a man who, after two months' (patient's statement) treatment with intramine and ferrivine still exhibited active infectious lesions—viz an ulcerated throat and an anal mucous patch.

We are Sir yours faithfully

"PIRATE" DOCTORS

To the Editor of THE LANCET

SIR.—In THE LANCET of June 17th Mr P Turner again publicly attacks doctors acting as locum tenens and as assistants for demanding a reasonable wage. Why? Surely when the wages of other occupations have gone up some by 150 per cent and when the cost of food, &c. has gone up doctors are equally entitled to raise their wage. He might as well attempt to argue that those doctors now in the army and who receive £1 £2 or £4 per day and allowances should not ask so much because those of them who hold public appointments still receive the whole or two thirds of the salaries from such posts. Let the principals employing assistants or locums do as others now do—increase their fees. No one objects to the resident Poor Law Medical officers increasing their charges from £120 to £200. No one objects to the fact that many of the leading surgical companies are now giving their surgeons £20 or £22 10s per month and full shore pay for their service. If there is too much marvellous sentimentalism about doctors during this war time this damned notion of doctors fleecing the public should be stopped.

I am Sir yours faithfully

ROBERT R. REED

Liverpool June 2nd 1916

The War.

THE CASUALTY LIST

The following names of medical officers appear among the casualties announced since our last issue —

Killed

Captain J Parker, R.A.M.C., attached to the Somerset Light Infantry

Died

Lieutenant G S Graham, R.A.M.C., graduated M.B., Ch.B. at Liverpool University in 1915, and joined the R.A.M.C. in February this year

THE HONOURS LIST

The following promotions and appointments of and awards to medical officers are announced —

C.B.—Col. F W G Gordon Hall, A.M.S. Lt. Col. E J W Mawhinney R.A.M.C.

C.M.G.—Temp. Hon. Maj. A C Valadier A.M.S. D.S.O.—Maj. E T Brown R.A.M.C. Lt.-Col. (temp. Col.) A C E Ke R.A.M.C. Temp. Capt. W Dawson, R.A.M.C. Capt. P F Gow I.M.S. Cap. W A Miller R.A.M.C., Spec. Res. (attd. 22nd Bn. P. Fes.)

M.B., Ch.B.—Temp. Capt. F C Atkinson Fleming R.A.M.C. (attd. 8th Bn. R. Innis Fus.) Temp. Lt. F E Marriott R.A.M.C. (attd. Hdqrs. 152nd Fld. Arty. Bde.) Temp. Capt. C M Brophy R.A.M.C. (attd. 15th Bn. Lond. R. T.F.) Capt. J A Galloway, Canadian A.M.C. (attd. 23rd Infy. Bn.) Capt. A E Ironside R.A.M.C., 4th Lond. Fd. Ambee. Temp. Capt. J M MacKenzie R.A.M.C. (attd. 6th Bn. Northd. Fusiliers T.F.) Temp. Lt. C C Oke, R.A.M.C., No 6 Fld. Ambee. Capt. W H Riddell I.M.S. Temp. Capt. M Peo R.A.M.C. Capt. J S Townley R.A.M.C. Capt. R S Townsend, I.M.S.

Second Class of the Indian Order of Merit—Sec. Cl. Senior Asst. Surg. Bhagwan Singh (attd. 1st Ferozepore Sikhs) I.M.S. 1st Cl. Sub. Asst. Surg. Ishar Singh, 168th Ind. Fld. Ambee. I.M.S. 1st Cl. Sub. Asst. Surg. Tika Ram (attd. 122nd Ind. Fld. Ambee.) I.S.M.D.

MENTIONED IN DESPATCHES

The names of the following should be added to those given in THE LANCET of June 24th as having been mentioned in the despatches relative to the operations in Egypt —

Australian and New Zealand Army Medical Corps. Lt.-Col. (temp. Col.) H C Maudsley Lt. Col. B J Newmarch. V.D. Lt. Col. J B McLean Lt. Col. P C Fenwick Maj. O E Maguire Maj. F T Bowerbank Capt. (temp. Maj.) T F Brown Cap. (temp. Maj.) D S Mackenzie.

Indian Subordinate Medical Department. Asst. Surg. H F Hogan 1st Class Sub-Asst. Surg. Tlooh Singh. Asst. Surg. Gurditt Singh Narain Singh.

OBITUARY OF THE WAR

HENRY JOHN SULLINGS KIMBELL M.R.C.S. ENG.,
LIEUTENANT ROYAL ARMY MEDICAL CORPS

Lieutenant H J S Kimbell, who died in London on May 22nd at the age of 36 years, entered St Bartholomew's Hospital in 1899

and took his medical qualification in 1907. He then held in succession house appointments at the Bedford County Hospital, King Edward VII. Hospital, Windsor, the City of London Living in Hospital, the Soho Hospital for Women and the Hospital for Nervous Diseases, Welbeck Street, with intervals of work as locum tenens in general practice. The war came as he was about to start in practice himself and he accepted a commission in the Royal Army Medical Corps. He was attached to Chatham and after serving there for some months was given charge of Pres. on Hall Woodhouse. While there he was called upon to contract blood poisoning from

A medical colleague writes of Lieutenant Kimbell "Endowed by nature above the average, his kind disposition and perfect manner made him universally popular, while his untiring energy in his work was an inspiration to those with whom he came in contact. Unsparing in service for others he refused to give up his work until the illness which proved fatal was so far advanced that his physical condition was too weak to throw it off. He will be greatly missed by his friends and patients."

MAURICE HENRY DE JERSEY HARPER, M.B.
B.S. DURH.,

SURGEON ROYAL NAVY

Surgeon M H de J Harper, who lost his life on H.M.S. *Queen Mary* in the naval action of May 31st at the age of 27 years, was the elder son of the late Rev H. B. Harper, a chaplain to the navy, and a nephew of Fleet-Surgeon A. F. Harper, R.N. He was educated at Elizabeth College, Guernsey, Pocklington and Trent Schools, entering Durham University, where he took his degree in June, 1914. He was then for a few months assistant medical officer at the Newcastle-on-Tyne City Asylum, Gosforth, leaving in September, 1914 to join the navy. His first appointment was at the Royal Naval Barracks, Chatham and then to H.M.S. *Thames* for service with the naval ambulance train. He joined H.M.S. *Queen Mary* in March, 1916.

Surgeon Harper was keen on all forms of sport, he was captain of the Association football team at Durham University and a member of the cricket eleven.

HERBERT LYNE GEOGHEGAN, M.D., B.Ch. Dub.
FLEET SURGEON ROYAL NAVY

Fleet-Surgeon H. L. Geoghegan, who was killed in action on H.M.S. *Black Prince* on May 31st at the age of 44, was one of a large family of Irishmen, all of whom are serving their country. He went to school at Neuwied in Germany and afterwards studied at Trinity College, Dublin, where he took his medical degrees in 1896. His service in the navy was hard and varied, for a long time he was in a mine-layer, where his life was one of dreadful anxiety and constant danger. In East Africa he had been a big game shooter and presented spoils of the chase to Haslar Hospital. Fleet-Surgeon Geoghegan's death will be a great loss to the service. A very senior medical officer wrote of him "He was one of the cheeriest of souls and kindest of men, he was also to my certain knowledge one of the very best of our medical officers upon whom it was always safe to place implicit confidence and feel sure that he would never fail in the very tightest of corners. We cannot afford to lose officers of this stamp." To this testimony one who knew him intimately since student days in Trinity College, Staff-Surgeon J. Keogh Murphy adds

"Fleet-Surgeon Geoghegan did not aspire to high professional degrees but wished to know his job, and he did know his job, as I have good reason to know at the Rotunda and elsewhere. He was a man who could be implicitly trusted. He was also a man who had a great gift of putting himself out of the case and thinking only of his patient's welfare. His personal attributes were extraordinary, always bright, cheery, alert, active, without a defect in his character, most popular, yet never seeking popularity, and absolutely adored by officers and men alike. No one who knew him would fail to realise what he would do in a tight corner, and what a help and comfort he must have been to many in the last moments of his existence." Fleet-Surgeon Geoghegan leaves a widow who is the sister of two senior medical officers in the service.

DEATHS AMONG THE SONS OF MEDICAL MEN

The following sons of medical men must be added to our list of those who have fallen during the war —

Lieutenant J D Champneys, Leicestershire Regiment, elder surviving son of Sir Francis H Champneys, of Littlemead, Nutley, Sussex

Lieutenant H R Page, Canadian Infantry, second son of the late Dr D Page, of the Local Government Board, Whitehall

Second Lieutenant W R Elphick, Indian Infantry, eldest son of the late Major H W Elphick, I M S

Major G H Taylor, 39th Garhwal Rifles Indian Army, second son of the late Surgeon Major A Taylor, I M S, Bengal Army

Second Lieutenant E G B Millson Bedfordshire Regiment, only son of Dr G Millson medical officer of health of the Borough of Southwark

Lieutenant H A Llewellyn, South Wales Borderers, son of the late Dr J D Llewellyn, of Bargoed, South Wales

Armourer Corporal J O'D Watson, only son of the late Lieutenant-Colonel J Watson R A M C

AUXILIARY ROYAL ARMY MEDICAL CORPS FUNDS

A meeting was held on Monday last at the Royal Army Medical College, Millbank, presided over by Sir Alfred Keogh, Director General of the Army Medical Staff, to discuss the scheme formulated by a Provisional Committee for the creation of benevolent funds to benefit the auxiliary branches of the Royal Army Medical Corps. The scheme was published in substance in THE LANCET last week. After some debate it was decided to hold a further meeting in a month's time, more opportunity being thus provided for consideration of the scheme.

PHYSICAL TREATMENT FOR DISABLED SOLDIERS

Major L Haden Guest, R A M C, sends us some notes on the treatment by mechano-therapy at the Hôpital Anglais in Nevers, an Anglo-French hospital established under his direction in November, 1914. The treatment is carried out in a separate building by Dr L J Phelan, an American practising in Paris as an expert in applied exercises, movements and massage. He employs a minimum of mechanical apparatus of the Zander type and a maximum of use of elastic cord exercisers. The latter have the great merit of economy as the cost of the apparatus for the treatment of 100 patients daily need not exceed £200.

The apparatus consists of a number of rubber cords and pulleys, and by adapting the position of the patient and the exerciser and by attaching the exerciser either to the hand or foot a very large variety of movements can be obtained. Special apparatus can be made for individual finger movements, flexion and extension of wrists, pronation and supination and so forth. The main characteristic of these apparatus is their simplicity. Movements of the hip are obtained partly by application of the exerciser to the foot and partly by the use of an inclined plane on which the patient lies. The plane is movable on runners placed below it and the patient pushes himself up by pressure with his feet. For passive movements of the ankle and knee in cases of great stiffness a mechanical apparatus on the Zander pattern cannot be dispensed with.

An analysis of 61 cases taken at random on Jan 3rd 1916 from the cases being treated at Nevers showed foot and leg 33, hand and arm, 22, shoulder, 6, hip 3. Some

cases have two injuries or more and these are separately counted. Treatment is given daily, with an average duration of ten minutes, but a number of cases can be treated at the same time. The length of treatment required by individual cases varies much with the nature of the injury and the condition of the patient but as a rough guide to the duration of treatment the following figures may be given: injury of hand one week, wrist, one to two weeks, elbow one month, knee, one month, adhesions (not affecting a joint) two to three weeks. At Nevers there have been 55 far 40 per cent of cures, 40 per cent greatly improved and 20 per cent not benefited. The possibility of progress or of cure can usually be discovered in from two days to a week's treatment. Cases for treatment should be sent as soon as possible after any open wounds have healed.

USE OF THE RED CROSS EMBLEM —The Secretary of the British Red Cross Society has sent us a memorandum (Form D 14) on the use of the red cross, defining, with the approval of the War Office, its employment on uniform placards, and motor cars. The essential points are as follows —

The emblem may be properly displayed on the uniform of the personnel of the Society and of recognised Voluntary Aid Detachments on the ambulances and other material including cases of stores and vehicles used solely for the conveyance of such stores on the official notepaper of and other official documents issued by the Society or by its affiliated subordinate branches, and on the badges granted by the Society for proficiency in nursing first aid &c. On the other hand, the use of the emblem on placards is regarded by the War Office as undesirable and can only be permitted on the understanding that such use is carefully watched and controlled. It must be limited to placards or notices issued by the Society or its affiliated subordinate branches for the purpose of raising funds for the Society. Should it be used on placards advertising entertainments, bazaars &c. the whole of the profits of such entertainments must be devoted to their entirety to the Society. In cases where the profits are divided, the emblem must on no account be used. The use of the Red Cross emblem in any form on private motor cars is prohibited even when those cars are being used for the conveyance of sick and wounded soldiers. Permission can only be given for a private motor-car to carry the emblem if it is used solely for the conveyance of sick and wounded soldiers and has been handed over to the military authorities. In such cases written permission from the military authorities is necessary. With regard to the use of the Red Cross flag private houses which have been handed over to the military authorities for the reception of sick and wounded soldiers are entitled to fly the flag when written authority for this purpose has been received from the War Office. In all cases where the Red Cross flag is flown over such establishments the Union Jack must be flown alongside it.

Chief constables have received instructions on the above lines, and they will bring to notice any irregular uses of the emblem.

THE CHILDREN IN BELGIUM —Starvation presses most hardly on the young, and the growing child, if stinted of food, may well grow up permanently enfeebled. The children of occupied Belgium are dangerously near the limit between bare necessity and starvation, and Mr John Galsworthy, in an eloquent letter which has been widely circulated, tells us that in the National Relief Committee's view, unless aid comes in much faster than is the case at present the children will starve. A special device for raising money to prevent this is that on July 10th all British boys and girls shall hold sports, give concerts or entertainments of some sort, the proceeds of which shall go to the children of Belgium. The medical profession has already responded generously to the special needs of the Belgian doctors and pharmacists and the appeal for the children will not fall on deaf ears.

Sir Thomas Anderson Stuart, Dean of the Faculty of Medicine of the University of Sydney, delivered a lecture on 'How to keep Fit' at the Liverpool Military Camp a year ago. This has now been reprinted and may be obtained from Mr A J Mallet, government printer, Melbourne. The lecture contains simple advice called from many sources suitable for the private soldier and of a kind readily understood.

Y M C A CONCERTS AT THE FRONT —The work done by the Y M C A in providing wholesome recreation for the fighting man whether at home or abroad is common knowledge. Since February 1915 the Ladies Auxiliary Committee under the chairmanship of Princess Victoria of Schleswig Holstein has arranged for a series of concerts in conjunction with the association. In all there have been 15 months over 2000 concerts have been given and a

concert party has gone as far as Malta and the East. Music is without question a hygienic agent and one which can be used without stint. To enable the concert parties to continue their beneficent work donations are needed and will be acknowledged by the organiser, Miss Lena Ashwell, at 36, Grosvenor street, London, W.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON—At examinations held recently the following candidates passed in the subjects indicated—

Surgery—H. N. Eccles (Sections I and II) Guy's Hospital, H. Lamb (Sections I and II) Manchester and Guy's Hospital, A. L. Malabre (Sections I and II) Washington and M. B. M. Tweed (Sections I and II) Guy's Hospital.
Medicine—H. Archer (Sections I and II) Bristol, R. H. Obadwick (Sections I and II) Leeds, A. L. Malabre (Sections I and II) Washington, L. A. B. Moore (Sections I and II) Guy's Hospital, E. G. D. Murray (Section II) Cambridge and St. Bartholomew's Hospital, and A. L. Watts (Sections I and II) Oxford and University College Hospital.
Forensic Medicine—H. Archer Bristol; O. P. Barber Charing Cross Hospital, A. L. Malabre Washington, M. M. Shaffi, London Hospital, and A. G. E. Wilcock St. George's Hospital.
Midwifery—L. A. B. Moore Guy's Hospital, E. G. D. Murray Cambridge and St. Bartholomew's Hospital, M. M. Shaffi London Hospital, and L. J. Vincent Cambridge and St. Mary's Hospital.
 The diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery and midwifery: H. Archer, H. N. Eccles, E. G. D. Murray and M. B. M. Tweed.

VICTORIA UNIVERSITY OF MANCHESTER—At examinations held recently the following candidates were successful—

Doctor of Medicine—J. A. Falser (with commendation), Francisco da Cunha, D. I. Dakeyne, Lovel Moss and William Stirling Jun.

UNIVERSITY OF DURHAM FACULTY OF MEDICINE—At the Convocation held on June 27th the following degrees were conferred—

Doctor of Medicine—T. O. Storey, M. B. B. S. (in absentia).
Doctor of Medicine for Practitioners of 15 years Standing—J. A. Barnes, M. R. O. S. L. R. O. P. H. E. O. h. Murray, L. R. O. P. & S. L. F. S. M. H. Smith, M. A. M. R. O. S. L. R. O. P.
Bachelor of Medicine (M.B.)—H. O. Broadhurst, Mary Russell Campbell, J. A. Charles, H. G. B. Dove, H. Evers, N. A. Martin, G. N. Metzger, B. A., D. O. Richards, M. R. O. S. L. R. O. P. W. O. F. Sinclair.
Bachelor of Surgery (B.S.)—H. O. Broadhurst, Mary Russell Campbell, J. A. Charles, H. Evers, R. A. Hooper, M. B. N. A. Martin, G. N. Metzger, B. A., D. O. Richards, M. R. O. S. L. R. O. P.
Bachelor of Hygiene (B. Hy.)—J. E. Baker, M. D. B. S.

The following received the Diploma in Public Health (D. P. H.)—

J. E. Baker, M. D. B. S.

The following received the Licence in Dental Surgery (L. D. S.)—

G. C. Adie and W. Hall.

A PROPOSED PRESENTATION TO SIR LEONARD ROGERS—It is proposed to present to the School of Tropical Medicine in Calcutta a portrait or bust, probably the latter, of Sir Leonard Rogers, in recognition of his untiring labour in obtaining contributions for the new building which is now ready. A representative committee consisting of the Hon. Surgeon General W. R. Edwards, C. B., C. M. G., Lieutenant Colonel W. J. Buchanan, C. I. E., Lieutenant Colonel C. R. M. Green, and Dr. W. Willoughby Kennedy, is in charge of the arrangements. £2 has been fixed as the maximum for a subscription, which may be paid to Messrs. Thacker, Spink and Co. 5 Government place, Calcutta to the credit of the Rogers Portrait Fund. The secretary of the fund is Lieutenant Colonel W. D. Sutherland, I. M. S.

THE HIGHER TRAINING OF MIDWIVES—A meeting of the Council for the Promotion of the Higher Training of Midwives was held under the presidency of the Lord Mayor, on June 27th at the Mansion House. The main object of the meeting was to raise money for building a school of midwifery at Woolwich which should be of a national character. A site has already been procured and £13,000 collected towards the building fund but another £13,000 are required. The work is at present being carried on at the Hospital for Mothers and Babies, Woolwich containing 14 beds only. The Lord Mayor in opening the meeting said that it was necessary for drastic measures to be taken if child life was to be preserved and the drain on the population caused by the war made up for. Lord Balfour of Burleigh said that according to the latest figures for England and Wales (the figures for Scotland were not yet available) about 1 in 10 of those born died under one year. Put in another way, there were more deaths among infants than

among adults between the ages of 40 and 60. This wastage of life was largely preventable and it was our duty to remedy the evil. A majority of the infants who survived suffered in after life from ailments due to lack of proper natal and ante natal attention. The two main things required were trained and efficient midwives and adequate accommodation for special cases. Lady Betty Balfour said that some kinds of saving were equivalent to reckless extravagance, and no greater extravagance could be conceived than to refuse the £13,000 which were required for a work of such national importance as the saving of infant life. If proper maternity homes were provided the infant mortality could be reduced by at least one half. Sir Dyce Duckworth, who said that we were far behind some of the continental nations in our measures for conserving infant life, made an earnest plea for the support of the work done by the Council for the Higher Training of Midwives. He remarked that a midwife required at least 12 months' training unless she had previously been a nurse. Dr. Barbara Tshaykovsky and Miss Alice Gregory also addressed the meeting.

THE LATE DR C. MACGOWAN KITCHING—Dr. Charles Macgowan Kitching, a well known medical man in Cape Town, died suddenly while he was conducting an operation at Somerset Hospital, to which he was visiting surgeon, on May 9th, at the age of 52. Dr. Kitching was the son of a Cape Town practitioner. He was closely associated with the Cape College of Music and with the Chamber Music Union. He leaves a widow, who is widely known locally as a vocalist.

DONATIONS AND BEQUESTS—Messrs. James Howell and Co., Limited, Cardiff, have forwarded a cheque for 500 guineas to the King Edward VII Hospital, Cardiff, in support of Sir William James Thomas's appeal for extensions of the institution.

The Albert Medal of the Royal Society of Arts has been awarded this year to Professor Elie Metchnikoff, of the Pasteur Institute, Paris, in recognition of the value of his inquiries into the nature of immunity. The annual report of the society estimated Professor Metchnikoff's discoveries as having contributed more than the work of any other living man to the control of infectious diseases.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

The Parliamentary Session

THE House of Commons since its reassembling after the Whitsuntide recess has been mainly occupied with finance. Several new provisions are being considered for inclusion in the Finance Bill. Before a clause authorising new taxation may be included in it a preliminary resolution in Committee of Ways and Means is required. Such a resolution has been passed authorising the proposed duty on petrol permits at the rate of 6d a gallon, but medical men will pay only half rates. One or two other important alterations in the terms of the Finance Bill are being brought forward. One of these will affect many professional men who make their savings in the form of endowment policies and deferred annuities. There has been an abatement of income tax allowed on account of the premiums on the policies, but the Government now desire to restrict this concession in the case of future policies to those which are spread over not less than 20 years and mature not sooner than when the insured reaches the age of 60. Some alterations have been introduced into the scale of the reduced rates of income tax payable by persons in the naval and military service of the Crown in respect of their pay. These give further concessions to the great majority of officers.

HOUSE OF COMMONS

TUESDAY, JUNE 20TH

National Health Insurance

Mr. CHARLES ROBERTS (who represents the National Health Insurance Commissioners) made a statement in Committee of Supply on the work which had been accomplished by the various commissions. He said that their work had been seriously interfered with by the war. They could not get funds in the shape of Exchequer grants for new services and fresh developments which might have been contemplated in normal times. Their staffs had been depleted by the calls made upon them for military service. The war had also brought new problems. They had carefully to watch the administration of benefits to soldiers who had been invalided. They had to deal with the medical attendance for the dependants of

TREATMENT OF TYPHUS FEVER BY THOROUGH VENTILATION

To the Editor of THE LANCET

SIR—In my Chadwick Lecture on typhus fever in THE LANCET of June 10th (p 1159) it is erroneously implied that Barraut, a Paris physician, was the first to introduce the system of thorough ventilation in the treatment of this disease, whereas the credit of having first advocated this treatment belongs to our distinguished countryman, Professor Sir Clifford Allbutt, who nearly 30 years previously both preached and practised it during the epidemic at Leeds in the year 1865-66

June 28th, 1916 I am, Sir, yours faithfully,
R O MOON

WAR VICTIMS' RELIEF IN FRANCE

THE work of the War Victims' Relief Committee of the Society of Friends in the devastated districts of the Marne and the Meuse continues in spite of the fact that nearly two years have elapsed since the line of the armies moved to any appreciable extent. At the maternity at Châlons sur Marne 262 babies were born up to the end of May, and 1152 persons treated in all. The convalescent home at Bettancourt-la Longue continues full of girls, many of them brought away from the dangers of the Rheims streets. In Bar le Duc the condition of the *émigrés* requires constant supervision from the nurses of the party. For all of these and for work in the villages of the whole district in many of which medical aid of any kind is unobtainable the help of an additional medical man or woman is urgently needed, as will be seen from a notice in our advertisement columns

KAFIR BEER

To the Editor of THE LANCET

SIR—Will you kindly have the accompanying specimen of kafir beer analysed for alcoholic strength and bacteriologically? The beer is made very crudely from a millet larger than that used in India for food. It is grown largely here by natives, ground down, fermented and drunk to excess. Intoxication lasts for three or four days after being once affected

I have observed the following effects directly attributable to its prolonged use: (1) painless enlargement of liver without jaundice (2) early arterio-sclerosis of visible arteries, (3) asthenopia with white optic discs (4) early cataract, (5) gastritis and dysentery in old and young respectively, (6) reflexes ultimately in comparatively young people suffer—e.g. knee jerks. I learn that in various parts of South Africa brewers use this kafir corn for making lager beer. Late last year a black rust has appeared in the corn which may influence the action of the beer

As regards the clinical pathology I do not think I can add to what I have given—I am, Sir, yours faithfully

WM ROBERTSON

St. Marks Cape Province South Africa May 22nd 1916

* The sample forwarded was inadequate for a systematic examination and was not even sufficient for the estimation of the alcohol alone. Our correspondent might consult one of the local Government analysts. The matter is quite interesting enough to have the examination suggested made.—ED L

THE DESTRUCTION OF COCKROACHES

To the Editor of THE LANCET

SIR—Dr I J H Holt quite ignores the possibility that cockroaches eat insect powder if free. In my experience many of the younger cockroaches were quite dead and his experiments were so contrived to prove that contact with the powder is not enough to cause death. But whether they are dead or not stirring insect powder along the joints of floors and walls has proved in my experience a very cheap and simple way of getting rid of cockroaches. I should think if some thing palatable was mixed with the powder the results would be even more satisfactory. Experiments in vitro such as Dr Holt's were very likely to lead to erroneous conclusions unless the hypothesis is created by them are tested carefully by other experiments done in a scientific manner a thing which apparently I have never even occurred to Dr Holt to do

I am, Sir, yours faithfully
Sidmouth June 25th 1916 G BULLOCK M D

A GERMAN MEDICAL EDITOR TO HIS CONTRIBUTORS

Dr J Schwalbe, editor of the *Deutsche Medizinische Wochenschrift*, addresses his contributors thus (1916, No 22) "I must ask my medical colleagues again further to be patient in regard to the publication of their work. It is self evident that the limitation of space due to the war on the one hand and the diminution of the printing staff on the other, must inevitably delay the setting up of the articles. This delay affects longer articles more than shorter ones. For this reason also contributors should restrict the volume of their MSS as far as possible, and avoid every addition in the way of tables or curves, &c, which is not absolutely necessary." In a similar request to our contributors we are on common ground with the German editor.

Veteran—The jurisdiction of the Central Midwives Board is confined to certified midwives and does not extend to persons who are acting as maternity nurses under the direction of a doctor. To constitute the offence of "covering an uncertified woman it is of the essence of the offence that she should be acting as a midwife.

Medical Examiner of Recruits has omitted to enclose his card.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES

It is most important that communications relating to the Editorial Business of THE LANCET should be addressed to "EDITOR" to THE EDITOR and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners. Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS not used.

MANAGER'S NOTICES

THE INDEX AND TITLE-PAGE TO THE LANCET

January to June, 1916

In view of the Government restrictions upon the supply of paper, and the shortage of paper quite apart from these restrictions, we cannot include, as usual, in all the copies of THE LANCET the Index and the Title-page which are due now. These are being prepared, and copies will be supplied gratis to subscribers who intimate their wish to receive them to the Manager, THE LANCET Office, 423, Strand, London, W C. Such application should please be sent in at once.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423 Strand, London, W C, are dealt with by them? Subscriptions paid to London or to local newsgents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

TO COLONIAL AND FOREIGN SUBSCRIBERS

Subscribers abroad are particularly requested to note the rates of subscriptions given on page 4.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied.

NEWSPAPERS FOR NEUTRAL COUNTRIES

Newspapers are not at present being sent forward to neutral European countries unless posted direct from the office of publishers or newsgents who have obtained permission from the War Office for this purpose. The Publisher of THE LANCET has obtained the required permission, and he will forward copies direct from the Office to any neutral country on receipt of instructions.

Battley's Liquors

First Class Award at
World's Industrial
Exposition,
New Orleans, 1883.
Bronze Medal,
St. Louis, 1901

The following preparations have for many years been used and prescribed by medical men, they are therefore thoroughly recommended both on account of their high therapeutical properties and their great purity as galenical preparations.

Liquor Opii Sedativus (Battley)

Dose 5 to 15 minims.

The Oldest and still the Best Hypnotic and Sedative
Twice the strength of Tinctura Opii B.P.
Safe in use. No disagreeable after effects
Composition always reliable

Liquor Cinchonæ Cord. (Battley)

Dose 2 to 15 minims.

The most reliable preparation of Cinchona Bark
Contains all the active principles of Yellow Bark
Will remain unaltered for a great length of time
being free from starch, etc.

Liquor Cinch. Pallidæ (Battley)

Dose: 2 to 15 minims.

A well known and useful preparation in Malarial
Diseases and in Convalescence after illness
Does not disturb the stomach

Liquor Secalis Cornuti (Battley)

Dose 20 to 60 minims.

Pre-eminent among Ergotic Preparations for Purity
and Strength and has proved to be unrivalled in the
following therapeutical actions—As an Emmena-
gogue and Ecbolic, in Post Partum Hæmorrhage,
as a Hæmostatic etc.

Battley's Liquors are issued in 2 oz., 4 oz., 8 oz. and 1 lb. bottles.

They are prepared according to the original process of the late Richard Battley

Hunterian Lecture

OR

THE DEVELOPMENT OF THE STRUCTURES ASSOCIATED WITH THE ROOF OF THE PRIMITIVE MOUTH

Delivered before the Royal College of Surgeons of England

By J. ERNEST FRAZER, FRCS Eng.,

LECTURER IN ANATOMY IN THE UNIVERSITY OF LONDON, LECTURER IN THE MEDICAL SCHOOL OF ST. MARY'S HOSPITAL, ETC.

MR. PRESIDENT, LADIES, AND GENTLEMEN.—The lecture which I have the honour of delivering before you deals with a subject about parts of which a good deal has been written from time to time, for there is an evident pathological importance in the developmental questions concerned, in addition to the purely anatomical interest that centres in their elucidation. The description that I propose to give is based largely on my own observations and it will, I hope, enable you to take into account one or two new points of view in your conception of the roof of the early mouth and its derivatives. I am dealing only with the roof of the common cavity, the cavity is derived from the oral sinus, and this in its turn is a modification of the stomodæum, which will thus provide a convenient starting point for the description.

FIG. 1.

Diagrams of embryonic plates with the amnion and ectoderm. The upper diagram shows the plate with the amnion and ectoderm, with the oral sinus indicated by a dashed line. The lower diagram shows the plate with the amnion and ectoderm, with the oral sinus indicated by a dashed line.

THE STOMODÆUM AND ORAL SINUS

The stomodæum is simply the recess or cleft between the overhanging prominence of the forebrain and the pericardium. When the walls of the neural groove begin their rapid growth they tend to bulge forward over their anterior limit and also to carry this margin forward beyond the confines of the embryonic rim reversing and folding under them the bucco-pharyngeal and pericardial areas of the embryonic plate (Fig. 1). The anterior end of the neural region thus projects beyond the level of the bucco-pharyngeal membrane turning itself forwards and downwards round its continuity with the upper end of the membrane and so coming to lie above the pericardium, the level of the

the prominence of the pericardium and separated by the bucco-pharyngeal membrane at its base from the foregut or primitive pharynx, a diverticulum of the general archenteric cavity that is included in the interior of the front part of the embryo which projects beyond the embryonic rim.

It is evident that a recess of this nature cannot be looked on as representing an early stage of the mouth of any vertebrate animal possessing jaws, and the stomodæum is really only the place where the mouth will be built up—the frame, as it were, within which the true mouth structures are about to appear. These new structures are to be found at a very early stage, in fact, it is doubtful I think, whether such a simple stomodæum as is shown in the diagram in Fig. 1 is ever really present in the human embryo. Such stages are only known to most of us by description and figures, for the specimens are few in number, and I am not one of the fortunate possessors of them. The earliest human embryo that I possess, after the stage of an embryonic plate, already shows a mandibular arch, although its forebrain is only just projecting over the bucco-pharyngeal area. On other grounds I consider this specimen abnormal, but examination of the records of other embryos tends to confirm me in my suspicions about the existence of a simple stomodæum, at any rate for more than a very brief time and with a very slight depth. The point need not detain us and it will be quite sufficient for us to recognise that the mandibular and maxillary processes those concerned with the formation of the true mouth make their appearance on the scene at a very early stage in development.

The mandibular arch, formed in the wall of the primitive pharynx immediately behind the ventro-lateral attachment of the bucco-pharyngeal membrane, grows forward (Fig. 2) on the upper aspect of the pericardium and forms a new floor for the deeper part of the cleft. At the same time the maxillary process extends forward and below the forebrain on each side, it is derived from the upper part of the mandibular arch and thus constitutes a sort of side wall to the deeper portion of the recess. In this way the oral sinus comes into existence at present only in the deeper part of the cleft between forebrain and pericardium but destined to enlarge rapidly as its boundaries grow. It is limited below by the mandible and on each side by the maxillary process and is separated at its base by the bucco-pharyngeal membrane from the cavity of the foregut, this membrane soon breaks down and disappears. Between the two maxillary processes however the central part of the stomodæal cleft still remains, with the posterior part of the forebrain forming its front and upper wall, and this can be taken as the earliest definite indication of Rathke's pouch.

EARLY STAGE IN DEVELOPMENT OF ROOF OF MOUTH

Fig. 3 shows the roof of the mouth in an embryo 4 mm. in which the mandibular arch has been covered by ectoderm, viewed from below. The ectoderm, on each side the two maxillary processes, slight elevations of this ectoderm, a little distance from the mandibular arch, the ectoderm, the area is a

FIG. 2.

Diagrammatic sketch of anterior end of embryo from the right showing the pharyngeal arches. The mandibular arch is seen joining the fellow above the pericardium, and the maxillary process is growing forward from its upper part. The oral sinus lies between these visceral structures of the two sides.

the early embryos. In later stages however and in some peripheral parts of the extending stratum, this method of ending and following its limits is not so valuable but here other aids can be often pressed into service. Possibly, in the future, one may find more delicate differential staining to be of use in this respect

GENERAL GROWTH OF ROOF AND NASAL CAVITIES

The maxillary growth continues in a forward direction. Fig 5 shows the roof in an embryo of 7 mm., in which Rathke's pouch is still widely open but evidently deeper, and the maxillary processes are better developed and longer coming very near to the olfactory areas. These areas are well marked on each side showing slightly raised borders, and the field of observation has extended beyond them so that they no longer look forward but only outward and downward. The extension of the field is due to the growth of the telencephalon from the front of the thalamencephalon, and the model shows very clearly that this is a single forward growth with only the very faintest lateral indications of secondary dilatations which will form the cerebral vesicles.

The eyes have been carried forward to some extent by the maxillary processes passing below them so that they rest on the front parts of these processes and their stalks form an angle with each other widely open in front. The whole optic outgrowth is surrounded by paraxial mesoderm, and the ocular muscles are represented behind and internal to the optic cup as a condensation in the same stratum. I imagine that this condensation also includes a very early stage of the ala orbitalis in its inner part, the matter, however, is of subsidiary importance.

FIG 5

Lower aspect of model of head of 7 mm human embryo. The maxillary processes are better marked and between them the pouch of Rathke is being buried in the paraxial stratum. The olfactory areas are evident surrounded by prominent lips. A new region in front of their level has been brought in being owing to the growth of the telencephalon.

The maxillary process is about to come into relation with the hinder end of the olfactory area and this is beginning to develop marginal lips, though it still retains the oval shape which characterized the earlier area and its floor is still somewhat convex. The growth of these lips or nasal folds or processes goes on apace. They are thickenings of the paraxial stratum and by rapid deepening on each side of the olfactory area they bury this between them so that the original area on the surface of the roof is now sunk in an olfactory pit of which the side margins are the inner and outer nasal folds respectively. These folds can be seen forming in Fig 6 gradually burying the olfactory surface. They are curled in front and also but to a very much less extensive degree at their hinder ends. The posterior

though present is even less well marked in the human embryo it may be found in specimens of about 8 mm. When the folds are formed each on one though longer and deeper than the inner ones owing to the slope on which they are built. The inner folds are connected by an extension of paraxial stratum where the paraxial growth has been the least vigorous than in the folds themselves and where there is consequently a depression on the surface. The maxillary folds with the depressed region between them are on the lateral process—a convenient term for use when referring to the whole central prominence from the olfactory pit.

The maxillary process comes up against the hinder end of the olfactory pit of its own side its mesoderm being applied to the paraxial mesoderm of both inner and outer nasal folds and to the low junction between them. The outer portion of the maxillary mass is evidently growing more rapidly than the rest, marking out a coarse margin to the roof and cavity and constituting the most markedly prominent part of the whole process, the front part of this at first applied more

FIG 6

Heads of two mouse embryos from models seen from the front and from the right. To show the growth of the nasal folds. Observe that the maxillary process comes up against the back of the inner as well as the outer fold.

laterally to the outer nasal fold, then passes below it to meet the inner fold which we have seen is at a lower level.

This development is shown in Fig 7, taken from embryos of 10 and 12 mm. The hinder, outer and lower aspects of the outer nasal fold in its posterior part are thus covered in by maxillary growth, and the corresponding part of the opening of the pit is closed by the extension across it of the maxillary process to reach the inner nasal fold thus forming the "primitive palate" of Dursy. But about the same time, sometimes before and sometimes after the growth of the maxillary process across the pit the lips of the two folds themselves meet and fuse, as is visible in both specimens in Fig 7.

We see then that the so-called "primitive palate" is formed mainly by extension of maxillary mesoderm between the outer and inner nasal folds but it also includes, above this, a separate meeting of paraxial mesoderm in these folds.

FIG 7

Stage 10 and 12 mm. The hind aspect of the outer nasal fold and maxillary process as seen in embryos of 10 mm and 12 mm. In the model from which the last drawn the maxillary process has been cut away so that the roof of the mouth cavity is exposed. Observe that the two nasal folds connect here in their inner parts and that the maxillary process extends across below this fused area to meet the inner nasal fold and more prominent nasal fold. This extension is with the inner and lower parts of the maxillary process and from the outer aspect of the maxillary process the nasal fold is formed and

themselves. At the hinder end of the olfactory pit maxillary mesoderm in relation with the outer fold is continuous with the associated (Fig 7) with the inner fold. The latter part of the maxillary extension is no thicker than the other but is a further layer converging with the fold as follows towards the front-nasal process where they meet and are laid over the hinder aspect of the process. Thus when the maxillary process and the folds are formed the maxillary process

the early embryo. In later stages however, and in some peripheral parts of the extending stratum this method of finding and following its limits is not so valuable but here other aids can be often pressed into service. Possibly, in the future, one may find more delicate differential staining to be of use in this respect.

GENERAL GROWTH OF ROOF AND NASAL CAVITIES

The maxillary growth continues in a forward direction. Fig 5 shows the roof in an embryo of 7 mm, in which Rathke's pouch is still widely open but evidently deeper, and the maxillary processes are better developed and longer, coming very near to the olfactory areas. These areas are well marked on each side, showing slightly raised borders and the field of observation has extended beyond them so that they no longer look forward but only outward and downward. The extension of the field is due to the growth of the telencephalon from the front of the thalamencephalon and the model shows very clearly that this is a single forward growth, with only the very faintest lateral indications of secondary dilatations which will form the cerebral vesicles.

The eyes have been carried forward to some extent by the maxillary processes passing below them, so that they rest on the front parts of these processes and their stalks form an angle with each other widely open in front. The whole optic outgrowth is surrounded by paraxial mesoderm and the ocular muscles are represented behind and internal to the optic cup as a condensation in the same stratum. I imagine that this condensation also includes a very early stage of the ala orbitalis in its inner part, the matter however, is of subsidiary importance.

FIG 5

Lower aspect of model of head of 7 mm human embryo. The maxillary processes are better marked and between them the pouch of Rathke is being buried in the paraxial stratum. The olfactory areas are evident surrounded by prominent lips. A new region in front of the eye level has been brought in being owing to the growth of the telencephalon.

The maxillary process is about to come into relation with the hinder end of the olfactory area and this is beginning to develop marginal lips, though it still retains the oval shape that characterised the earlier area, and its floor is still somewhat convex. The growth of these lips or nasal folds or processes goes on apace. There are thickenings of the paraxial stratum and by rapid deepening on each side of the olfactory area they bury this between them so that the original area on the surface of the roof is now sunk in an olfactory pit of which the side margins are the inner and outer nasal folds respectively. These folds can be seen forming in Fig 6 gradually burying the olfactory surface. They are united in front and also but to a very much less extent in degree at their hinder ends. The posterior region though present is even less well marked in the human embryo. It may be found in specimens of about 8 mm.

When the folds are formed each outer one though longer than the inner one is shorter than the inner one owing to the slope on which they are built. The inner folds are connected by an isthmus in the infra-nasal area where the paraxial growth has been more less vigorous than in the folds themselves. When the folds are complete it is a depression on the surface. The two folds with the isthmus of connection between them form the primitive palate. This is a depression on the surface of the roof of the mouth. The central part of the palate is the future central part of the palate. The folds are the future lips of the palate.

The maxillary process comes up against the hinder end of the olfactory pit of its own side its mesoderm being applied to the paraxial mesoderm of both inner and outer nasal folds and to the low junction between them. The outer portion of the maxillary mass is evidently growing more rapidly than the rest, marking out a coarse margin to the roof and cavity, and constituting the most markedly prominent part of the whole process, the front part of this, at first applied more

laterally to the outer nasal fold, then passes below it to meet the inner fold, which we have seen is at a lower level.

This development is shown in Fig 7, taken from embryos of 10 and 12 mm. The hinder, outer, and lower aspects of the outer nasal fold in its posterior part are thus covered in by maxillary growth, and the corresponding part of the opening of the pit is closed by the extension across it of the maxillary process to reach the inner nasal fold thus forming the 'primitive palate' of Dursy. But about the same time, sometimes before and sometimes after the growth of the maxillary process across the pit, the lips of the two folds themselves meet and fuse as is visible in both specimens in Fig 7.

We see then that the so-called 'primitive palate' is formed mainly by extension of maxillary mesoderm between the outer and inner nasal folds but it also includes, above this, a separate meeting of paraxial mesoderm in these folds.

FIG 7

Stage in the development of the primitive palate. The maxillary process as seen in embryos of 10 mm and 12 mm. In the model from which the left is drawn the maxillary process has been cut away so that the complete border in the line of paraxial mesoderm is visible. The maxillary process extends from the outer nasal fold to the inner nasal fold and the inner nasal fold is the future palate. The maxillary process is the future lip of the palate. The maxillary process is the future lip of the palate.

themselves. At the hinder end of the olfactory pit maxillary mesoderm in relation with the outer fold is continuous with the maxillary process (Fig 7) with the inner fold. This latter part of the maxillary extension is so thick like the other but is fused with the inner fold with its fellow towards the hinder aspect of the process. Thus, when the maxillary process is formed it reaches the inner fold and the maxillary tissue on

the inner fold and not the paraxial basis of that fold. The fusion of the epithelial covering of these two then forms an epithelial septum between them, in subsequent growth this epithelial lamina is widened out and thinned, forming the "bucco nasal membrane," and this membrane then separates the olfactory cavity from that of the mouth behind the primitive palate.

We can now examine the growth of the maxillary process in its various parts. In its first stage it grows forward deep to the lining of the mouth, in contact with the paraxial mesoderm and without any trace of an epithelial layer between them. In its relation with the outer nasal fold, however, it first applies its epithelial surface to a like surface of the fold, so that an epithelial lamina separates them at first, this is present in the 12 mm specimen (Fig 7), but it is soon broken through by the extending mesoderm and disappears, save in part of its deeper structure, where it seems to persist and form the rudiment of the lacrymal duct. Also an epithelial lamina necessarily exists at first between the primitive palate and the fronto-nasal process, but this is quickly destroyed as the maxillary mesoderm advances on the surface of this process, but here again one part remains as the bucco nasal membrane, showing plainly that no mesoderm extends across at this spot.

If we now compare this margin to the mouth which is being mapped out, we find that it corresponds in a sense with that shown in the 4 mm specimen (Fig 2) for the hinder and inner part of the olfactory region is in the field,

FIG 8

Longitudinal sections through the heads of embryos of 7 mm and 13 mm to show the great growth of the paraxial mesoderm particularly in association with the nasal region. The growth causes depression of the general level of the whole roof especially in front and has led to the pituitary being deeply placed with a long stalk. Notice also how it has affected the brain. *Ta* in front of the optic opening is in the thalamencephalon while *Tel* is in the telencephalon. The back part of the thalamencephalon is fixed in the pituitary region but the front part and the floor of the telencephalon are lifted up by the paraxial growth.

maxillary prominences mark its lateral boundaries and the opening of Rathke's pouch now reduced to a small passage is seen behind centrally placed between the bases of the maxillary processes.

But we have a new level for the roof. The great paraxial growth in the nasal region has depressed the front part and made the roof concave antero-posteriorly and the great maxillary growth at the sides has had the same effect in a coronal plane. The least departure from the old level is in the centre behind, and even here the growth of paraxial mesoderm has brought the roof down and the extent of displacement can be judged perhaps best by looking at the new level on sagittal section comparing it with the position of the roof of the fore-brain (Fig. 8) which might be taken to represent the old level. Comparison of the angle between this and the pharynx suggests that the paraxial growth in the front has not only depressed this part of the roof of the mouth but has also decidedly raised the front part of the fore-brain.

FURTHER MAXILLARY AND NASAL GROWTH

The roof in an embryo of 13-14 mm. is shown in Fig 9. The various processes and folds in the fronto-nasal region are now definitely locked together by extension of the maxillary mesoderm and destruction of any intervening epithelial septa. The bucco-nasal membrane has gone, not as the result of mesodermal growth, but probably as a consequence of some of the processes of preparation only some fragments of it remaining. It may persist to a certain

FIG 9

Inferior aspect of head of 13 mm embryo lower jaw removed. The impression of the short paired post-sphenoid bars is quite apparent in the roof. The pituitary opening is between them.

later stage, thinned out and stretched. Bryce figures it in an embryo of 16 mm., and I have seen its remains in one considerably older than this but it appears to be very vulnerable as soon as the nasal cavities begin to grow and does not as a rule survive for long. When it breaks down the result of opening is known as the "primitive posterior nares" and this can be considered to exist *in posse* if not *in esse* from the time the membrane comes into being. Such a posterior nasal opening is very small at first, as is seen in the figure and is situated far forward immediately behind and above the primitive palate.

The lateral portions of the maxillary process are slightly more differentiated than in the 12 mm specimen but if we

FIG 10

[illegible]

look at the other stage of 16 mm (Fig 10) it is seen that three distinct regions are visible here parts that will ultimately develop into the palps, the alveolar and labial ridges. The carnal defining boundaries of the maxillary region and are no longer in evidence as before.

epithelial ingrowths We see the same parts, better developed and more pronounced, in the 22 mm (Fig 11) and 28 mm (Fig 12) specimens The lip ridge is the most external and dependent, reaching a large size quickly, though it is at first incomplete centrally The alveolar ridge reaches the fronto-nasal process behind the labial fold and extends on to it in the same way, by mesodermal invasion, but its progress is not so rapid The palate fold reaches the

FIG 11

22 mm head in sagittal section showing the palate fold from within and the extent of the left nasal fossa

fronto-nasal process behind this, and there ends, not invading the process at any time

It is convenient to deal with the general growth of the nasal cavities at this point In the 13 mm embryo (Fig 9) the very small

posterior nasal openings—it is of no importance whether they are actual or potential passages—are placed far forward on the roof just above the primitive palate, they are a little larger in the 16 mm specimen I showed a few years ago that the increase in size of the nasal cavities takes place in an upward direction, the conclusion being based on the increasing angle between the level of the roof of the cavities and the base of the skull behind the pituitary region, this angle opens out from 130° to 160° or more, while that formed with the level of the floor remains practically fixed This means that the mesodermal walls of the cavities, growing rapidly where they lie below the level of the roof, elevate this roof without depressing the floor The mesodermal walls of the hinder part of the small cavity of the 12 mm embryo are maxillary in origin and form also the boundaries of the posterior opening, so in their growth *pari passu* with the paraxial portion of the walls the height of the opening is increased in an upward direction with that of the cavities Thus when we look at the openings in the 28 mm embryo (Fig 12) the difference in height is remarkable, but the addition is all in an upward direction the lower ends of each opening still resting on the primitive palate

An extension of this sort evidently implies that the openings enlarge upward at the expense of the roof of the mouth so to speak The septum is uncovered—or more properly discovered—by the two cavities as they grow up its basis is already laid down as paraxial condensations between the forebrain and the fronto nasal process, and as

FIG 12.

1. 28 mm embryo from below. 1. Labial alveolar and lip ridge. 2. The little tubercle at the end of the palate fold is the basis of the palate. Behind this is the pharyngeal extension of the palate fold. The interrupted line marks the position of the labial opening. The interrupted line marks the position of the labial opening. The interrupted line marks the position of the labial opening.

the cavities grow up on each side of the septum and then they solve the problem between the cavities. In other words the septum is discovered and brought into existence as a necessary result of the palatal upgrowth that takes place and the free edge or back of the septum a broad surface at first in the same way as the position of the roof of the mouth cavity which persists between the two external openings of the cavities

This is the way in which the septum comes into existence, there is never at any time a "downgrowth of the septum" in the sense of a structure growing into position into a cavity secondarily, nor is any downgrowth added to the septum made in the way described, and accounts of its formation based on the conception of a downgrowth are not in accord with the facts

The growth of the maxillary mesoderm that surrounds the posterior opening and forms the hinder part of the cavity leads to the back and lower parts of both walls of each cavity being composed of tissue of maxillary origin This mode of growth of the hinder portion of the early cavity seems to me to offer an explanation of those cases of so-called congenital occlusion of the posterior nares in which an obliquely deflected thick septum, sometimes bony in parts, extends upwards and backwards from the anterior part of the palatal floor of the cavity It is easy to imagine how some fault in the preliminary processes leads to the seat of active growth being situated above rather than below the level of the openings, so that these are left behind, so to speak, in the course of the growth, and a solid layer of maxillary tissue represents or takes the place of the opening lying in the plane of the early roof of the mouth The attachment of a septum of this sort, so far as I can gather from the descriptions given of them by pathologists, seems to me to be quite in accordance with the view that it represents a maxillary growth of this region which has failed to carry the opening with it in its extension

FIG 13

A schematic drawing founded on a specimen in which the palate had just closed to show the disposition of the folds. On one side the fold has been cut away at its base on the other side a portion is left in situ showing how it closes across to the middle line behind the fronto-nasal region to meet its fellow and fuse with the back of the septum. This part is the hard palate, the soft palate is indicated partly cut away behind this. The definitive posterior nares are seen to be the upper parts of the long opening that exists before the palate closes. 8 marks the position of Stenson's canal at the angle of junction of palate fold with fronto nasal process

Reconstructions of the capsule at various stages show that chondrification takes place and extends in this direction, preceded by mesenchymal condensation Chondrification may be looked on as evidence of attainment of the desired position and relations and occurs last at the upper part when this comes into position in the base of the skull

The extension of the nasal fossae reaches its end about the ninth week and the epoch is marked by the complete chondrification in its walls and by the closure of the palate folds behind it By this time the posterior openings are very long (Fig 13) extending from the primitive palate to the level of the top of the cavity of the mouth, and when the palate folds meet they fuse with the lower two-thirds to three-quarters of the free edge of the septum thus closing the corresponding extent of the openings and constituting new floors for the cavities here The upper one-quarter or so of the edge of the septum remains between the corresponding upper parts of the openings which now constitute the definite posterior nares Thus the posterior nares are only part of the elongated posterior openings that await the closing of the palate and these are in their turn but extensions of the primitive choanae of the earlier stages

THE PALATE FOLDS AND THEIR CLOSURE.

The palate folds can be said to form an inner edge to each maxillary process They are apparent in their posterior parts in the 12 mm embryo (Fig 7) as rounded folds

between the front portions of the tubo tympanic recesses and the mouth cleft separating the mandibular and maxillary processes. They are quite well marked in their entirety in the 16 mm embryo (Fig 10), and their farther growth can be seen in the 22 mm and 28 mm specimens (Fig 12). At 22 mm the inner view of the palate shows a flat vertical surface (Fig 11) which lies against a like surface of the tongue, while in the later stage this condition has been changed, the flat surface becoming hollowed in conformity with the rounded side of the tongue and the projection of the palate fold being now directed inwards and downwards and lying below the side of the mass of that organ.

This change, however, only occurs in the front part of the fold, the hinder portion, the future soft palate, being opposed to a still vertically disposed tongue, remains in a vertical position beside it. In the 28 mm specimen, moreover, there is apparently an indication of the distinction between hard and soft palate in the appearance of the fold itself, at any rate, there is no doubt about the meaning of the small tubercle at the hinder end of the fold below the tubal opening, for this is plainly the rudiment of the uvula of that side. The new ridge that has made its appearance behind this, continuing the line of the palate fold, is a forward growth from the third visceral arch (associated with the extension of this arch in the narrowing of the Eustachian tube) which comes secondarily into relation with the maxillary palate fold proper, it forms the pharyngeal extension or posterior pillar of the fauces and need not concern us further.

The palate folds reach the sides of the fronto nasal process by their pointed anterior extremities and extend no further. When they close across below the septum their anterior parts are folded round this process and meet behind it, as shown in the scheme in Fig 13, leaving the process exposed between their extreme front ends. Even this exposed area is partly covered in as the folds grow larger and thicker and its surface becomes wrinkled so that epithelial nests and pillars remain for some little time between its buried surface and the folds that overlap it. Finally, only the small area that constitutes the incisive papilla is left uncovered. Stenson's canals mark the angles of the original separation between the process and the folds. But, in order to meet below the septum, the folds must leave their position below the tongue, which occupies the cavity of the mouth and lies in contact with its roof, and must find their way above this organ, this change requires some consideration in detail.

CHANGE IN POSITION OF THE PALATE FOLDS

Although the details of the formation of the palate have been known for about 50 years, it is only within the last 15 years or so that suggestions have been made concerning the factors which may be at work in bringing about the change in position of the folds with reference to the tongue. In this time many hypotheses have been advanced to account for the change.

W. His, the first to contribute a separate study of the question attributed the process to the withdrawal of the tongue from the upper part of the cavity and from between the folds as the result of muscular action both in the tongue and on the jaw causing depression of the whole structure.

Fick in his later views thought that the definitive palate is not formed from the "palate folds," but from small ridges which he described in pig embryos situated above these. Anna Pölzl also, looked for the explanation of the position above the tongue in the occurrence of a new growth in a higher situation, with atrophy of the original folds. But she likewise describes the tongue as growing forward out of the space between the folds as the result of growth of the associated structures of the face and not from muscular action.

Schorr considered that the folds are opened out by a lively growth near their lower surfaces in the angles between them and the alveolar masses. At the same time the tongue is elongated and depressed and a complicated interaction of forces between tongue and folds leads to the latter coming on to the upper surface of the tongue. Pohlmann and others have thought that the change might result from a fresh modelling of the parts with widening of the ventral wall and curving inward of the side walls. Fick ascribed the change of plane of the folds to the rapid growth of the tongue compelling it to emerge from the narrower upper

part of the general cavity. Frets does not think that active muscular contraction is at all likely, but considers the change to be "the expression of tension adjustment within the tongue and between the tongue and processes."

Michio Inouye divides the phenomenon into two phases. In the first the tongue withdraws from its situation below the base of the skull and allows the hinder portions of the folds to come above it. In the second the consequent increased tension of the front parts of the folds and proportionate pressure on the tongue lead to movements of this organ and the jaw, depressing the tongue and allowing the folds to slide over it. K. Peter adopts the view of Inouye and refers the change to the withdrawal of the tongue and subsequent active contraction.

In this summary of the views held by various writers there are certain opinions which we may at once rule out of consideration. Thus, so far as concerns suggestions founded on supposed new formations at a higher level than the palate folds, the fact that such growths have never been seen is enough to condemn the views built on them. The ridges described by Fick had been known for many years before he studied them, and their ultimate fate had been pointed out by Dursy. Moreover, the difficulty of getting rid of the palate folds remains unsurmounted. No support, too, is to be found in actual observation for the hypotheses advocated by Pohlmann. Fick's explanation of the phenomenon could only be accepted as such, I think, under a false conception of the conditions prevailing in the mouth. It is not necessary for the tongue to descend from the back of the septum for a distance greater than the thickness of the palate fold, and to get below the folds the tongue would have to pass at any rate temporarily, into a smaller space—if the mouth is closed, as it ought to be in a normal embryo.

The Role of the Tongue

The remaining views, with the exception of Schorr's theory of the force inherent in the palate fold centre round the tongue as concerned in the change of plane of the folds, ascribing to it in one way or another the greater share in bringing about the occurrence. The opinions which I formed on this subject while working on the development of the nose some years ago also allot to the tongue the main rôle in the undertaking.

In the early stages this organ occupies practically the whole cavity of the mouth, being in contact with the roof and thus with the back of the septum as this comes into evidence, for, as I have shown this is simply the part of the roof left undisturbed between the two nasal openings as they extend upward. But the tongue not only grows intrinsically but is also carried downwards and forwards as a result of the growth and elongation of the lower jaw, so it comes about that while it is still in contact with the greater part of the roof its upper and back portion has come away from the upper part of the roof. The tongue is in contact normally with all the walls of the mouth completely filling that part of the cavity in which it is contained. The direct examination of sections does not give us, I venture to think, a correct idea of the way in which the growing tongue is pressed against the neighbouring structures, the effect of dehydration and of fixing reagents appears to alter it to a considerable extent.

The palate folds are in what might be termed a sub-horizontal position below the tongue. They are not vertical except in their hinder parts. A description or figure of the folds in a vertical position would indicate in my opinion that the section went through the region of the soft palate or that the tongue was much shrunk or depressed as the result of separation or as a whole by the opening of the mouth accidentally or as a post mortem change.

Here I may mention that the only figure given by Schorr in support of his views affords no indication of the condition or position of the tongue nor have I been able to find in his account any means of forming an opinion on this matter or on the condition of the embryos. One might be tempted to open to criticism. Not only does it seem hardly possible to imagine a force so strong in a section in the folds as to be able to lift this up against the force of contraction of the tongue in position by its area of contraction, but it may be found in my experience in the folds of the tongue (as they are abnormally) turned down and then in the case of the head where I would be tempted to look for the same cause as I have explained.

His based his opinions on an embryo which he described, but I have not been able to obtain the original description. Peter, however, gives a figure of one section and from this I would have little hesitation in considering the specimen abnormal in the sense I have indicated above. A like criticism, however, cannot be applied to Inouye's specimen.

How the Change in Position is Brought About

The relatively small size of the folds below the tongue, compared with their thickness and general increase after they have come above that organ, is an indication that in the first situation they are compressed and their growth inhibited. Their anterior ends are very small, each coming to a point on the end of the fronto-nasal process. The tongue is carried down as a whole with the elongation of the lower jaw, and about the ninth week its tip comes behind and below the fronto-nasal process—i.e., it is carried below the level of the folds which are attached to the upper and back part of this process. The passage of the tongue between the folds here is favoured by the small size of their front ends, and now that the end of the wedge is metaphorically and almost literally introduced it seems to me easy to conceive the change of plane of the folds thus initiated going on to its complete fulfilment. Possibly the tongue may be stimulated to an irregular contraction by the change of pressures that ensue from its tip coming below the fronto-nasal region, and this may be the explanation of the condition present in one of Inouye's embryos in which the tongue was below the fold on one side, under conditions that evidently differed from those obtaining in His's specimen. Or such a factor as want of perfect symmetry may lead to a one-sided preference in the slipping up of the folds. But, whatever view may be thought likely concerning this point, the action itself seems to me to be of minor importance, being only the individual way of carrying on the movement started by the forward growth of the tongue. Having arrived below the folds, the tongue is now necessarily at a slightly lower level in a somewhat wider space and thus room above the organ is provided in which the folds can meet below the septum of the nose. The folds are now free to grow, and apparently do grow with considerable speed, and it is not long before they meet above the tongue. They are at first a little distance from the septum, resting on the tongue, but this structure seems to share in the opportunity for growth provided by the change of position and soon begins to press the folds against the septum to which they adhere.

But the tongue was not in contact with the upper part of the septum which on its lingual aspect is part of the roof, so that the folds here are not brought against the septum but remain on the tongue and join to form the soft palate. Thus not only the change of position of the folds but also their attachment to the septum and the general arch of the whole palate depend ultimately on the agency of the tongue for their existence in a mechanical sense.

The naso-pharynx is that part of the cavity left above the soft palate brought into existence by the descent of the tongue originally but probably enlarged subsequently and secondarily. It seems very doubtful whether it can be claimed as a derivative from the mouth cavity proper, probably it would be more correct to describe its cavity as being originally part of that of the foregut.

The portion of the mouth cavity which lies above the level of the open palate folds is frequently termed the "cavum naso-pharyngeum" or pharyngo-nasale apparently (at any rate in some cases) from a mistaken conception of the developmental changes taking place in the neighbourhood. If it is understood that the whole nasal fossa is extra oral in its formation with all its turbinal masses and accessories it is evident that the only portion of the cavum that is taken into the final nasal cavity lies between the margin of the nasal opening and the upturned fold which is about to close this opening. This is a negligible amount of space and is only represented in the nasal cavity by the extreme lowest portion of the inferior meatus just above the floor and behind the anterior foramina.

THE MESODERMAL DEVELOPMENT

In illustrations of the general distribution of the two mesodermal strata have been given throughout the preceding account of the formation of the roof. We have seen that the paraxial layer is thickened centrally, the thickening passing into the outer growth round the nasal and optic regions and also laterally, and the immediate surroundings of these

special sense organs are developed in this stratum. The maxillary stratum is distributed over the surface of the other, ultimately covering it completely on its inferior aspect except where the original fixed area of the primary stomodæum is developing as the pituitary body. The palate folds are purely maxillary, the primitive palate is mainly maxillary but to a small extent paraxial above this, while the maxillary tissues which cover the septal (central) portion of the roof and the margins of the two posterior openings extend from here for a considerable distance on to the corresponding walls of the nasal fossae.

The premaxillary part of the upper jaw develops in the maxillary portion of the primitive palate, and the vomer is laid down in the maxillary layer on the septum, as is also the paravomerine cartilage and (probably) the recurved portion of the cupola of the cartilaginous capsule which lies against the septum. The septal maxillary stratum here is continuous, inside the capsule and round the posterior part of the cupola, with that on the back part of the outer wall of the fossa, in which the palate bone and greater part of the inferior turbinate are formed. The maxilla and its palatine process, on the other hand, belong to the main maxillary mesenchyme outside the walls of the capsule. The details of the development of these several bones have been given from time to time by Fawcett whose researches have become a standard reference on this matter and need not be recapitulated here.

Failure of Maxillary Growth and Causation of Clefts

It is evident that the bones concerned in forming the visible roof of the mouth are maxillary in their origin, and all considerations seem to me to point to failure in the driving power of the maxillary growth as the great underlying factor in the causation or persistence of the common clefts of the palate and alveolus. The failure is naturally more evident in the outlying parts of its extension, the parts which reach their position late and secondarily. The real nature of this "power of growth" is, of course, at present quite beyond our ken, nor have we any clear ideas as yet about the conditions which affect it, but it seems to me quite possible—however improbable—that some means may yet be found by which this growing power may be artificially stimulated and augmented and even made available as a therapeutical adjunct.

In the neighbourhood of the primitive palate the maxillary mesoderm extends on to the fronto-nasal region by a process of invasion under the epithelial lining. There is no application of one epithelial surface to another a sort of extension of the conditions present when the maxillary and inner nasal processes first meet, but a direct extension, into the latter region of cells from the former process, the stratum thus formed lying superficial to the original paraxial mesoderm of the fronto-nasal process.

In the region of the lip the maxillary invasions advance from each side and meet in the middle as pointed extensions (see Fig. 10) of the layer which enclose an angle open downwards, this rapidly closes and completes the central part of the lip. Thus leaving out of account those cases that may be referred to absence of the fronto-nasal process it would seem that central fissures of the upper lip indicate failure in the maxillary stratum. Normally the philtrum marks the junction of the two labial fronto-nasal extensions of the maxillary layer.

The same mode of spread serves for the extension of the alveolar eminences toward the middle, it is a slower process here and allows the general shape of the underlying fronto-nasal region to show for some time through the thin covering layer (see Fig. 12). The alveolar eminences do not quite reach the middle line but a narrow tract between them connects the labial ridge with the area between the palate folds (Fig. 13). When the teeth appear the continuity of the tract seems to be interrupted and the front portion remains as the frenum of the lip rendered prominent by the deepening of the alveolar labial sulcus beside it.

Want of time keeps me from entering on a consideration of the dentition in this region but I may point out that the position of the line of early ectodermal thickening is shown in Fig. 12 and that it seems probable that only the central incisor is formed on the fronto-nasal region and although

² This ridge is, though conveniently termed, "alveolar" but it is to do with the formation of the permanent alveolus. It appears to be composed of the tissue which are formed to close the clefts of the palate.

the lateral incisor may be placed over the situation of the original junction between this and the maxillary process, yet it is not improbable that this may be a situation which it acquires secondarily.

The position of a complete cleft in the alveolar region would necessarily be between the fronto-nasal and maxillary processes. A double complete cleft, if originally complete and due to the total failure of the maxillary process to bridge the chasm, would imply the absence of any maxillary tissues in the so called "separated premaxilla," save that reaching it from behind along the septum. Under these circumstances interest centres round the nature of the bony structures found in the separate fragment. It must be remembered that an incomplete cleft may be complete so far as maxillary mesoderm is concerned, the connexion only persisting between the paraxial nasal folds. On the other hand, a cleft or fissure may have had maxillary tissues bridging it to some extent at one time, subsequently giving way, as Keith has pointed out, and thus a maxillary basis of some sort may be present in an apparently separate portion attached to the

FIG 14

Two schemes to illustrate the general relations between paraxial and maxillary strata in (A) the middle and (B) the hinder regions of the roof. In both the left side is supposed to indicate a later stage than the right. In A, p and v are the two strata. In B L and r are the early lingula and pterygoid respectively, and G is the Gasserian ganglion. Palate folds and tongue are not shown.

septum. Such varying circumstances must be taken into account in any effort to place the bones found in the fragment for they may theoretically be of modified maxillary or modified paraxial nature. It is rather fascinating to think of the possibility of past powers of the paraxial mesoderm coming to life again when the maxillary superstratum is removed—a revival of lost industries which have faded under the peaceful penetration of the external growth, to illustrate the process by a metaphor which comes home to us directly in these days.

In the intermediate portion of the roof the conditions might be represented as in Fig 14, A. The paraxial layer is thick, especially in the middle, where the condensation of the central bar is apparent. Below this the maxillary mesenchyme forms a lateral mass on each side, below the paraxial surroundings of the eye, and thus away toward the middle where it lies below the central bar. Later, as the nasal cavities grow upward and backward, this region is modified as shown on the left side of the figure and the central paraxial bar finds itself in the nasal septum. Nasal upgrowth is not so marked a feature in the mouse and the changes, though of the same nature are accordingly modified to some extent. In the fowl the enormous eye and corresponding paraxial development is correlated with a comparatively shallow maxillary stratum and the absence of upward extension of the nasal cavities leaves the central bar as an interorbital septum. The ossifications in the maxillary mesoderm have the distribution they would possess in the mammal if they occurred here before the nasal extension had taken place.

The Hinder Region of the Roof

The hinder region of the roof is from some points of view its most interesting part. For brevity it may be described as it is illustrated in Fig 14 B. The maxillary mesoderm is in position and in it occurs the chondrification which signals the appearance of the outer pterygoid plate and the lingula while the lingula is formed internal root of the alisphenoid while the lingula is formed internal root of the alisphenoid and later becomes attached to these in the same stratum and later becomes attached to the paraxial bars and to the otic capsule. It is interesting to recall that Parker in a lecture delivered here more than 30 years ago claimed the lingula as the representative remnant in the human skull of the parasphenoid of lower types—a contention which, I confess, seemed to me one hard to support before following its formation in the maxillary

mesenchyme, the stratum in which the parasphenoid is also developed.

The inner part of the great wing is laid down first in cartilage, and the rest of this bone is not called for till the cerebral vesicles require support. This is afforded by outward extension of the great maxillary mass below each vesicle, the intervening paraxial tissues being converted into the membranes covering the wing. The development of this part goes beyond the limits of our subject, however, and it need only be said that the alisphenoid appears in its parts successively from within out. The chondral portion exists alone for a considerable time, supporting the Gasserian ganglion and its branches and the outer part of the wing is added in membrane when it is required, all the parts being derived from maxillary mesenchyme. The details of the chondrification and ossification have been given by Fawcett in his well-known papers.

In the centre of the hinder region Rathko's pouch is at first a widely open and rather shallow recess (See Fig 3). The pouch is deepened, not by upgrowth of its fixed wall but by rapidly increasing thickness of the paraxial stratum which lies round its mouth. Thus the opening is elongated and narrowed into a stalk while the upper part still remains as a large sac, fixed to the rounded lower angle of the forebrain at first, but soon separated from this.

The paraxial thickening forms two short but well defined bars, one on each side of the stalk, these undergo prechondral change as distinct bars, but are later fused in a single plate of cartilage giving passage to the stalk. Later still, however, the paired nature reasserts itself in the ossification of this part which forms the postsphenoid, and is traversed by the remains of the pituitary stalk or by its canal, the situation of the canal is not between post and pre sphenoid, but through the former as has been affirmed by Erdheim and Haberland and lately by Cope. The stalk is implanted in the roof of the mouth below the post sphenoid bars, surrounded by paraxial mesoderm, but this part is gradually dislocated forward and elongated below the central paraxial thickening. The dislocation is associated with the growth of the central parts of the maxillary layers along the back of the septum, and possibly also with the formation of the roof of the pharynx behind it. The result

FIG 15

Three stages in the front and post of the pouch separated from the brain. In the first the two concavities are filled by mesoderm growing up in the direction of the arrows. In the others the epithelial folds are seen first forming along the lower border. Before the end of the third month the outgrowths have appeared all over the surface and constitute definite antero-lateral folds.

is that a long epithelial strand is drawn out from the postsphenoidal region in a forward direction so far that its point of implantation becomes situated on the central part of the roof between the nasal opening—i.e. on the back of the septum (see Fig 13) and when the palate is completed this point is just above the hinder limit of the fusion of the folds with the septum. The extended epithelial strand disappears later with the exception of a small fragment which persists below the sphenoid as a solid epithelial mass frequently a small cyst.

Development of Pituitary Body

While these changes are going on the uncompressed part of the pouch above the post-sphenoidal bars is undergoing conversion into the antero-lateral lobes of the pituitary body. Its front wall is separated from the apposed surface of the forebrain by ventro-lateral ingrowth of paraxial mesoderm, so that, when looked at from the front, it presents two concavities looking downwards and forwards and outwards (Fig 15), and separated from each other by a prominent central keel. While this separation is proceeding, the true infundibular outgrowth occurs from the brain just above the upper limit of the pouch, and projects back resting centrally on its upper surface. The position of this outgrowth suggests to the observer that it comes from that part of the brain which was originally (see Fig 1) the front end of the

FIG 16

Semi-diagrammatic view of cranial base in 13 mm embryo. *ac* = Post-sphenoidal bars in prechondral state. *cc* = condensations round notochord at a deeper level represented as showing through a semi-transparent superficial layer. A little further back the optic nerve and carotid are seen piercing this layer and around these the condensation of the orbito-sphenoid is shown by short lines extending out over the anterior dural veins. Two areas of prechondral change are shown near the nerve and artery. Further back the paraxial stratum has been removed, the prechondral mass of the external pterygoid is seen between the artery and vein and that of the lingula between the artery and post-sphenoid bar. The great superior nerve passes below the artery and the third and sixth are above the vein.

suggested to us in the human embryo by the relation of the neural growth to the upper wall of Rathke's pouch.

As soon as the mesodermal growth has freed the pouch from the apposed neural wall the upper part of the pouch commences to grow up on each side of the infundibular process forming a couple of hollow cornua and this is the first true upgrowth to be found in its history. The antero-lateral lobes are formed by sprouts growing from its front wall into the mesoderm occupying the concavities here. The growth begins below and its area of origin extends upward finally involving the cornua which have by this time grown up and met over the back of the neural process. The lumen of the main pouch remains widely patent while these growths are appearing and its back and upper wall is applied to the infundibular or neural lobe which is not bulbed as is free end of the posterior wall of the pouch shown as a local abortive outgrowth but remains in place as a wall of ectoderm as an epithelial layer applied to the neural lobe and as a lining apparently the part inferred as of Henle.

GENERAL DEVELOPMENT OF ANTERIOR PART OF CRANIAL BASE

Fig 16 is a semi diagrammatic rendering of the right half of part of the model of the 13 mm head, somewhat flattened out to exhibit the necessary structures. In the posterior part the two post-sphenoidal bars are shown, developed in paraxial mesoderm, and the stalk of the pituitary is seen between them, the developing gland being taken away with the brain. Outside this region are seen the prechondral rudiments of the inner parts of the great wing lying in the maxillary mesoderm below the carotid artery and primary head vein, while the third and sixth nerves are passing above these vessels in the paraxial stratum. The outer part of the great wing will not be called into existence for some time to come, and its only representative probably is to be found in the sections as a maxillary mass slightly developed just to the outer side of the Gasserian ganglion.

The paraxial stratum has been removed in this area, but has been left *in situ* in front of it, and can be divided for descriptive purposes into two layers—superficial or neural, next the brain, and deep, next the maxillary stratum. The optic stalk and carotid artery are shown passing through the superficial layer near one another, and the layer is condensed round them and shows a prechondral state in two places here. The condensation extends centrally and outwards over the veins of the anterior dural plexus (Streeter), suggesting a covering formation for these veins. Evidently we have here the early rudiment of the lesser wing of the sphenoid.

Further forward the superficial layer thins considerably, and is represented in the figure as semi transparent, so that the underlying condensations round the eye and nose are apparent through it situated at a lower level in the deep layer. These condensations are continuous at their upper parts, the connexion being also visible on the outer surface of the head.

As the nasal cavities grow upwards and backwards the deep condensations are brought up towards the level of the lesser wing. As they get into position the connecting mesenchyme between them comes against the lesser wing, and the cartilaginous sphenoid-plate is formed in it, this disappears later and is replaced by the orbital plate of the frontal. The superficial layer covering the condensations forms the immediate coverings of the brain.

Thus we see that the base, as far back as and including the lesser wing, is formed in paraxial mesoderm but, behind these wings the paraxial stratum has been thinned out and carried back to provide the membranes of the tentorium, &c., leaving the maxillary stratum to supply the bony support for the temporo-sphenoidal pole in the interval between paraxial lesser wing and paraxial orb capsule. In other words the great wing of the sphenoid ought from its origin to be included among the bones of the visceral skeleton which help to build up the complete skull.

EDINBURGH FACULTY OF MEDICINE THE ADMISSION OF WOMEN.—The Senatus Academicus of Edinburgh University decided at their meeting on June 29th to recommend to the University Court that the classes in the Faculty of Medicine should be open to women. The new Principal, Sir James A. Ewing presided over the meeting which was attended by a majority of the members nearly 50 being present. Up to the present the University has offered a medical qualification to women without taking any responsibility for their education which has to be obtained in an extra-mural institution. There are now 170 students at the Women's School of Medicine at the Surgeons' Hall, over 60 of these having entered during the past year. The accommodation at the school is overtaxed while the depletion of the attendance at the University classes owing to the war leaves plenty of room there. It is shown that a number of professors in the University are favourable to the admittance of women to the medical classes and opposition to the scheme is based more on the fear of an innovation and its practical working than upon any question of principle. It is suggested that the introduction of women might tend to reduce the number of male students. Another difficulty which has been raised is the possible shortage of clinical material since there is only one large infirmary in the city but it is thought that Leith Hospital and the county hospitals might be made available.

the lateral incisor may be placed over the situation of the original junction between this and the maxillary process, yet it is not improbable that this may be a situation which it acquires secondarily

The position of a complete cleft in the alveolar region would necessarily be between the fronto-nasal and maxillary processes. A double complete cleft if originally complete and due to the total failure of the maxillary process to bridge the chasm, would imply the absence of any maxillary tissues in the so called "separated premaxilla," save that reaching it from behind along the septum. Under these circumstances interest centres round the nature of the bony structures found in the separate fragment. It must be remembered that an incomplete cleft may be complete so far as maxillary mesoderm is concerned, the connexion only persisting between the paraxial nasal folds. On the other hand, a cleft or fissure may have had maxillary tissues bridging it to some extent at one time, subsequently giving way, as Keith has pointed out, and thus a maxillary basis of some sort may be present in an apparently separate portion attached to the

FIG 14

Two schemes to illustrate the general relations between paraxial and maxillary strata in (A) the middle and (B) the hinder regions of the roof. In both the left side is supposed to indicate a later stage than the right. In A, p and v are the two strata. In B L and P are the early lingula and pterygoid respectively and G is the Gasserian ganglion. Palate folds and tongue are not shown

septum. Such varying circumstances must be taken into account in any effort to place the bones found in the fragment, for they may theoretically be of modified maxillary or modified paraxial nature. It is rather fascinating to think of the possibility of past powers of the paraxial mesoderm coming to life again when the maxillary super stratum is removed—a revival of lost industries which have faded under the peaceful penetration of the external growth, to illustrate the process by a metaphor which comes home to us directly in these days

In the intermediate portion of the roof the conditions might be represented as in Fig 14, A. The paraxial layer is thick, especially in the middle, where the condensation of the central bar is apparent. Below this the maxillary mesenchyme forms a lateral mass on each side, below the paraxial surroundings of the eye, and thus away toward the middle where it lies below the central bar. Later, as the nasal cavities grow upward and backward, this region is modified as shown on the left side of the figure and the central paraxial bar finds itself in the nasal septum. Nasal upgrowth is not so marked a feature in the mouse and the changes, though of the same nature are accordingly modified to some extent. In the fowl the enormous eye and corresponding paraxial development is correlated with a comparatively shallow maxillary stratum and the absence of upward extension of the nasal cavities leaves the central bar as an interorbital septum. The ossifications in the maxillary mesoderm have the distribution they would possess in the mammal if they occurred here before the nasal extension had taken place

The Hinder Region of the Roof

The hinder region of the roof is from some points of view its most interesting part. For brevity it may be described as it is illustrated in Fig 14 B. The maxillary mesoderm is in position and in it occurs the chondrification which signals the appearance of the outer pterygoid plate and indicates the appearance of the lingula is formed internal root of the alisphenoid, while the lingula is formed internal root of the alisphenoid, and later becomes attached to these in the same stratum and the otic capsule. It is interesting to recall that Parker in a lecture delivered here more than 30 years ago claimed the lingula as the representative remnant in the human skull of the parasphenoid of lower types a contention which I confess seemed to me one hard to support before following its formation in the maxillary

mesenchyme, the stratum in which the parasphenoid is also developed

The inner part of the great wing is laid down first in cartilage, and the rest of this bone is not called for till the cerebral vesicles require support. This is afforded by outward extension of the great maxillary mass below each vesicle, the intervening paraxial tissues being converted into the membranes covering the wing. The development of this part goes beyond the limits of our subject however and it need only be said that the alisphenoid appears in its parts successively from within out. The chondral portion exists alone for a considerable time, supporting the Gasserian ganglion and its branches, and the outer part of the wing is added in membrane when it is required, all the parts being derived from maxillary mesenchyme. The details of the chondrification and ossification have been given by Fawcett in his well known papers

In the centre of the hinder region Rathke's pouch is at first a widely open and rather shallow recess (see Fig 3). The pouch is deepened, not by upgrowth of its fixed wall but by rapidly increasing thickness of the paraxial stratum which lies round its mouth. Thus the opening is elongated and narrowed into a stalk, while the upper part still remains as a large sac, fixed to the rounded lower angle of the forebrain at first, but soon separated from this

The paraxial thickening forms two short but well defined bars, one on each side of the stalk, these undergo prechondral change as distinct bars, but are later fused in a single plate of cartilage giving passage to the stalk. Later still however the paired nature reasserts itself in the ossification of this part, which forms the postsphenoid and is traversed by the remains of the pituitary stalk or by its canal, the situation of the canal is not between post and pre sphenoid, but through the former, as has been affirmed by Erdheim and Haberland, and lately by Cope. The stalk is implanted in the roof of the mouth below the postsphenoid bars surrounded by paraxial mesoderm but this part is gradually dislocated forward and elongated below the central paraxial thickening. The dislocation is associated with the growth of the central parts of the maxillary layer along the back of the septum, and possibly also with the formation of the roof of the pharynx behind it. The result

FIG 15

Three stages in the front aspect of the pouch, separated from the brain. In the first the two convoluted sides are filled by mesoderm growing up in the direction of the arrows. In the others the epithelial folds are seen first forming along the lower border. Before the end of the third month the outgrowth has become all over the surface and constitute definite antero-lateral lobes

is that a long epithelial strand is drawn out from the postsphenoidal region in a forward direction so far that its point of implantation becomes situated on the central part of the roof between the nasal openings—i.e. on the back of the septum (see Fig 13), and when the palatal folds at this point are just above the hinder limit of the fold of the folds with the septum. The strand of epithelial tissue disappears later with the exception of a small fragment which persists below the sphenoid as a solid cartilage or more frequently a small cyst

Development of Pituitary Body

While these changes are going on, the uncompressed part of the pouch above the post-sphenoidal bars is undergoing conversion into the antero lateral lobes of the pituitary body. Its front wall is separated from the apposed surface of the forebrain by ventro-lateral ingrowth of paraxial mesoderm, so that, when looked at from the front it presents two concavities looking downwards and forwards and outwards (Fig 15), and separated from each other by a prominent central keel. While this separation is proceeding, the true infundibular outgrowth occurs from the brain just above the upper limit of the pouch, and projects back resting centrally on its upper surface. The position of this outgrowth suggests to the observer that it comes from that part of the brain which was originally (see Fig 1) the front end of the

It is known that a number of professors in the University are favourable to the admittance of women to the medical classes and opposition to the scheme is based more on the fear of an innovation and its practical working than upon any question of principle. It is suggested that the introduction of women might tend to reduce the number of male students. Another difficulty which has been raised is the possible shortage of clinical material, since there is only one large infirmary in the city, but it is thought that Leith Hospital and the county hospitals might be made available.

AN INVESTIGATION INTO SOME OF THE EFFECTS OF THE STATE OF NUTRITION OF THE MOTHER DURING PREGNANCY AND LABOUR ON THE CONDITION OF THE CHILD AT BIRTH AND FOR FIRST FEW DAYS OF LIFE

BY G F DARWALL SMITH, M.A., B.M., B.Ch. Oxon.,
F.R.C.S. Eng.,

ASSISTANT OBSTETRIC PHYSICIAN ST GEORGE'S HOSPITAL, LONDON
PHYSICIAN GENERAL LYING-IN HOSPITAL, LAMBETH S.E.
SURGEON TO OUT PATIENTS SAVANITA FREE HOSPITAL
FOR WOMEN, MARLBOROUGH ROAD N.W.

THIS investigation embodies the results of an attempt to estimate some of the effects of the state of a mother's nutrition during pregnancy and at the time of labour on the condition of her child at birth and during the first few days of life, as deduced from statistics obtained from the lying-in hospitals of London and Dublin. The total number of cases investigated was 6162 of which 3721 represented hospital experience in London and 2441 similar experience in Dublin. The method adopted to obtain the statistics was to send out a number of printed cards to the hospitals, on each of which were entered the particulars of one case by the resident medical officer or registrar of the hospital. The cases were not selected in any way. The information thus obtained has been carefully classified and arranged to enable certain conclusions to be drawn if possible.

The most difficult thing in the investigation has been to determine what was the state of a mother's nutrition so that comparisons might be made between different cases. An attempt has been made to arrive at this in three ways.

1. The weights and heights of the patients have been taken soon after they came to the hospitals and before delivery. From these data tables were constructed showing the average weight of a mother for any given height, the London and Dublin mothers being treated separately, because it was found that the women of these two cities showed a distinct difference in this respect. A similar height and weight ratio was also taken after excluding all those cases which were shown by criteria 2 and 3 mentioned below, to be in a state of either extremely good or extremely bad nutrition, but the average figures so obtained differed so little from those obtained by the first method that the state of nutrition, so far as this criterion is concerned, has been deduced from the former tables only. Unless there were at least 50 women of any given height from whom the average weight could be computed, the cases were discarded as useless for the purpose of this investigation. The maximum number of women of any given height in London in the series under examination was 580, with a height of 5 ft. 2 in. and in Dublin 325 with a height of 5 ft. 2 in. The average figures obtained in this way were checked by comparing the weights at labour of 52 women with their weights two months later when involution was presumably complete. In this way the average loss of weight was ascertained, and by adding this amount to the average weight for any given height of a woman in ordinary circumstances as given in Hutchison's tables a result was obtained which agreed very closely with the average figures obtained from the cases weighed at the time of labour. It may be noted in passing that the women whose state of nutrition was good according to criteria 2 and 3 appeared to lose more weight during the puerperium than did those whose state of nutrition was bad according to the same criteria, but the total number investigated in this way was too small to allow any certain conclusion to be drawn on this point.

2. The second way in which an attempt was made to arrive at the state of nutrition of a woman at the time of labour was by getting the medical officer in charge of her to record his impression as to whether this was good, average, or bad on the card referring to her case.

3. The third way was by having recorded on the card each woman's own account of the amount of food she had been able to obtain during her pregnancy as being good, average, or bad.

It was noticeable that a large percentage of those women whose state of nutrition was bad according to criteria 2 and 3

could not be weighed and measured when they arrived at hospital, owing either to the advanced state of labour or to some complication such as accidental hemorrhage. Cases in which the malnutrition was due to disease have been excluded.

As regards the height and weight ratio, those cases have been classed as good whose weight exceeded the average weight of women one inch taller, those cases as bad whose weight fell short of the average weight of women one inch shorter, all other cases have been classed as average. It will be seen from the figures that the number of cases with average nutrition as tested by this height and weight ratio is smaller than that of those with either good or bad nutrition. This of course, means that many average cases are included in the good and bad classes and the effect is to understate rather than overstate the conclusions drawn from the good and bad classes, but if the average class had been enlarged by using a different method the number of cases with bad nutrition according to all three criteria would have been so small as to be valueless.

In the light of the above three criteria of the state of a woman's nutrition all the cases available have been divided into classes as follow—

A 3, Cases in which the height and weight ratio, the observed state of nutrition, and the nutritional history are all bad.

B 3, Cases in which the height and weight ratio, the observed state of nutrition, and the nutritional history are all average.

C 3, Cases in which the height and weight ratio, the observed state of nutrition, and the nutritional history are all good.

A, Cases in which the height and weight ratio is bad.
B, Cases in which the height and weight ratio is average.
C, Cases in which the height and weight ratio is good.
In this classification it will be noticed that most stress is laid on the height and weight ratio.

Influence of the State of Nutrition of the Mother on the Death of the Child during or before Labour

The percentage of dead births in the case of women of bad nutrition (A 3) was 7.7 per cent. out of a total of 65 cases. If all the cases suffering from accidental hemorrhage could have been weighed and measured, the percentage would probably have been still higher. In the class of average nutrition (B 3) the dead births are 1.1 per cent. out of a total of 183 cases. In the class of good nutrition (C 3) the percentage is 1.9 for 860 cases. It is noticeable that though the class of lowest nutrition has by far the highest percentage of dead births the class of average nutrition has a lower percentage than the class of good nutrition. This may be due to the increased weight of the babies in the class of good nutrition (*vide infra*). It has to be observed however that the last-named class is much larger than the two others. When the height and weight ratio alone is considered, the dead births are 2.1 per cent. for 2280 cases of bad nutrition, 1.1 per cent. for 978 cases of average nutrition and 1.7 per cent. for 1824 cases of good nutrition again a rather higher percentage for those of good than for those of average nutrition.

Influence of the State of Nutrition of the Mother on the Prematurity of Labour

In considering these figures it must again be remembered that many mothers with accidental hemorrhage could not be weighed and measured. Here 11.9 per cent. of 59 labours were premature in the class of bad nutrition (A 3). In the class of average nutrition (B 3) 2.7 per cent. out of 183 cases. In the class of good nutrition (C 3) 1.3 per cent. out of 818 cases. For cases grouped by the height and weight ratio alone when the mothers' nutrition was bad 5.3 per cent. were premature out of 2225 cases, when it was average 2 per cent. out of 959 cases, and when it was good 2.7 per cent. out of 1795 cases.

Influence of the State of Nutrition of the Mother on the Weight of the Full-time Infant at Birth

For this purpose the birth weight has been considered to be above the average if it exceeded 8 lb. to be of average value if between 6 lb. and 8 lb. and to be below the average if below 6 lb. In the class of bad nutrition (A 3) out of 50 babies 10 per cent. were above and 14 per cent. below

the average weight. In the class of average nutrition (B 3) out of 177 babies 12.4 per cent. are above and 11.3 per cent. are below. In the class of good nutrition (C 3) 40.1 per cent. are above and 3.1 per cent. below out of 836 babies. In this case a state of maternal nutrition above the average seems to have a very marked effect in increasing the baby's weight, whereas a bad state of nutrition on the part of the mother has less effect in decreasing it than might have been expected, since the figures for the class of bad nutrition and for that of average nutrition are not very widely removed from one another. When the height and weight ratio alone is taken into consideration, out of 2103 babies of mothers with bad nutrition 17.7 per cent. were above the average weight and 11.8 per cent. below, out of 943 babies of mothers with average nutrition 23.4 per cent. were above and 8.1 per cent. below, and out of 1839 babies of mothers with good nutrition 34.6 per cent. were above and 4.1 per cent. below.

Influence of the State of Nutrition of the Mother on Post-natal Mortality of Infants

Out of 3593 babies born in the London hospitals 2.1 per cent. died during the first ten days of life. If, however, those cases are excluded to which the height and weight ratio could not be applied, in which the mother's malnutrition was due to disease, or in which the baby died as the result of injury, malformation, or syphilis, there remain 3015 babies, of whom 1 per cent. died. As contrasted with this, out of 45 babies born in London of mothers with bad nutrition (A 3) 6.66 per cent. died, out of 184 babies of mothers whose state of nutrition was average (B 3) 0.5 per cent. died, and out of 323 babies of mothers with good nutrition (C 3) 0.3 per cent. died. Where the height and weight ratio alone was bad the death rate was 1.3 per cent. for 1177 babies, where it was average 0.5 per cent. for 589 babies, and where it was good 1 per cent. for 1249 babies. In the Dublin hospitals during the first eight days of life the death rate for all the 2439 babies was 2.5 per cent. and for the 1703 cases which could be classified 0.3 per cent. On the other hand the death rate for the 12 Dublin babies of mothers with bad nutrition (A 3) was 8.3 per cent., where the mother's state of nutrition was average (B 3) none of the 8 babies died, where it was good (C 3) 0.8 per cent. of 512 babies died. When the height and weight ratio alone is considered 0.9 per cent. of 934 babies of mothers with bad height and weight ratio died, 0.4 per cent. of 241 babies born of mothers with average height and weight ratio, and 0.8 per cent. of 533 babies born of mothers with good height and weight ratio.

Influence of the State of Nutrition of the Mother on the Progress of the Child after Birth

For the purpose of ascertaining the progress of the babies after birth their weights on the tenth day in the case of London babies and on the eighth day in the case of Dublin babies (since the Dublin babies were not as a rule kept in hospital after the eighth day) have been compared with their birth weights, and the change in weight has been contrasted with the average weight curve given by Holt.¹ The condition has been labelled "satisfactory" if the progress has been equal to or better than that shown on this curve. In all other cases it has been labelled "unsatisfactory" or the death of the child has been recorded. Separate tables have been made out for those babies who were fed entirely on the breast for those who were fed entirely artificially and for those fed partly on the breast and partly artificially (mixed fed). Those cases have been excluded in which the mother's malnutrition was due to disease and those in which the baby died or failed to thrive as the result of injury, malformation, or syphilis. These also have been excluded. Premature babies have been tabulated separately but they were too few in number to afford data for conclusions of any value.

To take for the first time babies fed on the breast in the London hospitals there were 25 babies of mothers with bad nutrition (A 3), of these 64 per cent. progressed satisfactorily and 34 per cent. failed to thrive. None died. When the mother's nutrition was average (B 3) out of 103 babies 61.1 per cent. progressed satisfactorily, 33 per cent. failed to thrive and 0.9 per cent. died. When the mother's nutrition was good (C 3) out of 251 babies 70.1 per cent. progressed satisfactorily, 29.9 per

cent. failed to thrive and none died. When the cases are classified by the mother's height and weight ratio alone, of 818 babies born in London of mothers whose height and weight ratio was bad, 65.9 per cent. flourished, 33.7 per cent. failed to thrive, and 0.4 per cent. died. When the mother's height and weight ratio was average out of 418 babies 62.2 per cent. flourished, 37.5 per cent. failed to thrive, and 0.2 per cent. died. When the height and weight ratio was good, of 836 babies 63.2 per cent. flourished, 36.6 per cent. failed to thrive and 0.2 per cent. died. The Dublin cases in the classes of bad and average nutrition were so few that conclusions can hardly be drawn from them. Moreover, it is noticeable that mixed breast and artificial feeding seems to be resorted to much more readily in London, when the baby does not seem to be thriving, than in Dublin. Possibly this is partly due to the fact that the London babies stay longer in hospital, so that their progress can be better gauged.

To the figures for the full-time babies fed partly on the breast and partly artificially the same criticisms, of course apply, and the Dublin cases are so few as to be almost valueless. There were only 9 full-time babies of this kind in London whose mother's nutrition was bad (A 3). Of these, 33.3 per cent. flourished, 55.5 per cent. failed to thrive and 11.1 per cent. died. When the mother's nutrition was average (B 3) out of 66 babies 42.4 per cent. flourished, 57.6 per cent. failed to thrive, and none died. When the mother's nutrition was good (C 3), out of 53 babies 32.8 per cent. flourished, 67.2 per cent. failed to thrive and none died. Of the London babies, when the mother's height and weight ratio was bad, 30.4 per cent. flourished, 68.4 per cent. failed to thrive, and 1.3 per cent. died out of 237 babies. Similarly when the height and weight ratio was average, the figures are 35.9, 64 and 0 per cent. for 142 babies, and 30.3, 69.4 and 0.3 per cent. when the height and weight ratio was good.

The numbers of the full-time babies who were fed entirely artificially were too few to allow of any useful deductions being drawn.

With regard to the infantile death-rate before lactation was established the combined figures for London and Dublin give 51 babies whose mother's nutrition was bad (A 3) with a death rate of 2 per cent., 184 babies of mothers with average nutrition (B 3) with a death rate of 0 and 827 babies of mothers whose nutrition was good (C 3) with a death rate of 0.2 per cent. When the height and weight ratio alone is considered the death rate was approximately the same for all classes.

From the foregoing figures it does not appear that the state of nutrition of the mother at the time of labour and during her pregnancy has any marked influence on the progress of 'mixed fed' and breast-fed babies during the first eight or ten days of life. On the other hand the death rate of babies before lactation is established may perhaps be higher when their mothers are really badly nourished. It must be remembered that from the time of labour until their discharge from hospital all the mothers were presumably receiving an ample diet.

Influence of the State of Nutrition of the Mother on her Capacity of Suckling

The percentage of breast-fed babies is very much higher in Dublin than in London and this quite apart from the question of mixed feeding, since the percentage of artificially fed babies—that is of mothers who had no milk at all—is much higher in London than in Dublin. Both in London and in Dublin however the state of the mother's nutrition does seem to have a definite influence on her capacity of suckling. Of a total of 3533 babies born in London 73.21 per cent. were breast-fed, 24.32 per cent. were mixed fed, and 2.47 per cent. artificially fed. Of 2352 Dublin babies 95.51 per cent. were breast-fed, 1.23 per cent. were mixed fed, and 0.25 per cent. artificially fed. These figures exclude babies who died before lactation was established and those who were not breast-fed owing to extraneous causes, such as tubercle, syphilis, sepsis, or ripples affecting the teat. Of the 23 babies in London whose mother's nutrition was bad (A 3) 65.8 per cent. were breast-fed, 23.4 per cent. mixed fed, and 5.3 per cent. artificially fed. The figures have to be compared with 62.7, 35.7 and 0.6 per cent. for 153 babies whose mother's nutrition was average (B 3), and with 72.5, 17.9 and 2.5 per cent. for 316 babies whose

AN INVESTIGATION INTO SOME OF THE EFFECTS OF THE STATE OF NUTRITION OF THE MOTHER DURING PREGNANCY AND LABOUR ON THE CONDITION OF THE CHILD AT BIRTH AND FOR FIRST FEW DAYS OF LIFE

BY G F DARWALL SMITH, M.A., B.M., B.Ch. Oxon.,
F.R.C.S. Eng.,

ASSISTANT OBSTETRIC PHYSICIAN ST. GEORGE'S HOSPITAL, LONDON
PHYSICIAN GENERAL LYING-IN HOSPITAL, LAMBETH S.E.
SURGEON TO OUT-PATIENTS SAMARITAN FREE HOSPITAL
FOR WOMEN, MARYLEBONE ROAD, N.W.

THIS investigation embodies the results of an attempt to estimate some of the effects of the state of a mother's nutrition during pregnancy and at the time of labour on the condition of her child at birth and during the first few days of life, as deduced from statistics obtained from the lying-in hospitals of London and Dublin. The total number of cases investigated was 6162 of which 3721 represented hospital experience in London and 2441 similar experience in Dublin. The method adopted to obtain the statistics was to send out a number of printed cards to the hospitals, on each of which were entered the particulars of one case by the resident medical officer or registrar of the hospital. The cases were not selected in any way. The information thus obtained has been carefully classified and arranged to enable certain conclusions to be drawn if possible.

The most difficult thing in the investigation has been to determine what was the state of a mother's nutrition so that comparisons might be made between different cases. An attempt has been made to arrive at this in three ways.

1. The weights and heights of the patients have been taken soon after they came to the hospitals and before delivery. From these data tables were constructed showing the average weight of a mother for any given height, the London and Dublin mothers being treated separately, because it was found that the women of these two cities showed a distinct difference in this respect. A similar height and weight ratio was also taken after excluding all those cases which were shown by criteria 2 and 3, mentioned below, to be in a state of either extremely good or extremely bad nutrition, but the average figures so obtained differed so little from those obtained by the first method that the state of nutrition so far as this criterion is concerned, has been deduced from the former tables only. Unless there were at least 50 women of any given height from whom the average weight could be computed, the cases were discarded as useless for the purpose of this investigation. The maximum number of women of any given height in London in the series under examination was 580, with a height of 5 ft 2 in. and in Dublin 325 with a height of 5 ft 2 in. The average figures obtained in this way were checked by comparing the weights at labour of 52 women with their weights two months later when involution was presumably complete. In this way the average loss of weight was ascertained, and by adding this amount to the average weight for any given height of a woman in ordinary circumstances, as given in Hutchison's tables, a result was obtained which agreed very closely with the average figures obtained from the cases weighed at the time of labour. It may be noted in passing that the women whose state of nutrition was good according to criteria 2 and 3 appeared to lose more weight during the puerperium than did those whose state of nutrition was bad according to the same criteria, but the total number investigated in this way was too small to allow any certain conclusion to be drawn on this point.

2. The second way in which an attempt was made to arrive at the state of nutrition of a woman at the time of labour was by getting the medical officer in charge of her to record his impression as to whether this was good, average or bad on the card referring to her case.

3. The third way was by having recorded on the card each woman's own account of the amount of food she had been able to obtain during her pregnancy as being good, average or bad.

It was noticeable that a large percentage of those women whose state of nutrition was bad according to criteria 2 and 3

could not be weighed and measured when they arrived at hospital, owing either to the advanced state of labour or to some complication such as accidental hæmorrhage. Cases in which the malnutrition was due to disease have been excluded.

As regards the height and weight ratio those cases have been classed as good whose weight exceeded the average weight of women one inch taller, those cases as bad whose weight fell short of the average weight of women one inch shorter, all other cases have been classed as average. It will be seen from the figures that the number of cases with average nutrition, as tested by this height and weight ratio is smaller than that of those with either good or bad nutrition. This of course means that many average cases are included in the good and bad classes, and the effect is to understate rather than overstate the conclusions drawn from the good and bad classes, but if the average class had been enlarged by using a different method the number of cases with bad nutrition according to all three criteria would have been so small as to be valueless.

In the light of the above three criteria of the state of a woman's nutrition all the cases available have been divided into classes as follow—

A 3, Cases in which the height and weight ratio, the observed state of nutrition, and the nutritional history are all bad.

B 3 Cases in which the height and weight ratio, the observed state of nutrition, and the nutritional history are all average.

C 3, Cases in which the height and weight ratio, the observed state of nutrition, and the nutritional history are all good.

A, Cases in which the height and weight ratio is bad.

B, Cases in which the height and weight ratio is average.

C, Cases in which the height and weight ratio is good.

In this classification it will be noticed that most stress is laid on the height and weight ratio.

Influence of the State of Nutrition of the Mother on the Death of the Child during or before Labour

The percentage of dead births in the case of women of bad nutrition (A 3) was 7.7 per cent. out of a total of 65 cases. If all the cases suffering from accidental hæmorrhage could have been weighed and measured the percentage would probably have been still higher. In the class of average nutrition (B 3) the dead births are 1.1 per cent out of a total of 183 cases. In the class of good nutrition (C 3) the percentage is 1.9 for 860 cases. It is noticeable that though the class of lowest nutrition has by far the highest percentage of dead births the class of average nutrition has a lower percentage than the class of good nutrition. This may be due to the increased weight of the babies in the class of good nutrition (*vide infra*). It has to be observed, however, that the last-named class is much larger than the two others. When the height and weight ratio alone is considered, the dead births are 2.1 per cent for 2280 cases of bad nutrition, 1.1 per cent for 978 cases of average nutrition and 1.7 per cent for 1824 cases of good nutrition, again a rather higher percentage for those of good than for those of average nutrition.

Influence of the State of Nutrition of the Mother on Pre-maturity of Labour

In considering these figures it must again be remembered that many mothers with accidental hæmorrhage could not be weighed and measured. Here 11.9 per cent of 59 labours were premature in the class of bad nutrition (A 3). In the class of average nutrition (B 3) 2.7 per cent out of 183 cases. In the class of good nutrition (C 3) 1.3 per cent out of 848 cases. For cases grouped by the height and weight ratio alone when the mother's nutrition was bad 5.3 per cent. were premature out of 2225 cases, when it was average 2 per cent out of 978 cases and when it was good 2.7 per cent out of 1795 cases.

Influence of the State of Nutrition of the Mother on the Weight of the Full-time Infant at Birth

For this purpose the birth weight has been considered to be above the average if it exceeded 8 lb. to be of average value if between 6 lb. and 8 lb. and to be below the average if below 6 lb. In the class of bad nutrition (A 3) out of 50 babies 10 per cent. were above and 14 per cent. below

the average weight. In the class of average nutrition (B 3) out of 177 babies 12.4 per cent. are above and 11.3 per cent. are below. In the class of good nutrition (C 3) 40.1 per cent. are above and 3.1 per cent. below out of 836 babies. In this case a state of maternal nutrition above the average seems to have a very marked effect in increasing the baby's weight, whereas a bad state of nutrition on the part of the mother has less effect in decreasing it than might have been expected, since the figures for the class of bad nutrition and for that of average nutrition are not very widely removed from one another. When the height and weight ratio alone is taken into consideration, out of 2108 babies of mothers with bad nutrition 17.7 per cent. were above the average weight and 11.8 per cent. below, out of 943 babies of mothers with average nutrition 23.4 per cent. were above and 8.1 per cent. below, and out of 1839 babies of mothers with good nutrition 34.6 per cent. were above and 4.1 per cent. below.

Influence of the State of Nutrition of the Mother on Post natal Mortality of Infants

Out of 3693 babies born in the London hospitals 2.1 per cent. died during the first ten days of life. If, however, those cases are excluded to which the height and weight ratio could not be applied in which the mother's malnutrition was due to disease, or in which the baby died as the result of injury, malformation, or syphilis, there remain 3015 babies, of whom 1 per cent. died. As contrasted with this, out of 45 babies born in London of mothers with bad nutrition (A 3) 6.66 per cent. died, out of 184 babies of mothers whose state of nutrition was average (B 3) 0.5 per cent. died, and out of 328 babies of mothers with good nutrition (C 3) 0.3 per cent. died. Where the height and weight ratio alone was bad the death rate was 1.3 per cent. for 1177 babies, where it was average 0.5 per cent. for 589 babies, and where it was good 1 per cent. for 1249 babies. In the Dublin hospitals during the first eight days of life the death rate for all the 2439 babies was 2.5 per cent., and for the 1708 cases which could be classified 0.3 per cent. On the other hand the death rate for the 12 Dublin babies of mothers with bad nutrition (A 3) was 8.3 per cent., where the mother's state of nutrition was average (B 3) none of the 8 babies died, where it was good (C 3) 0.8 per cent. of 512 babies died. When the height and weight ratio alone is considered, 0.9 per cent. of 934 babies of mothers with bad height and weight ratio died, 0.4 per cent. of 241 babies born of mothers with average height and weight ratio, and 0.6 per cent. of 533 babies born of mothers with good height and weight ratio.

Influence of the State of Nutrition of the Mother on the Progress of the Child after Birth

For the purpose of ascertaining the progress of the babies after birth their weights on the tenth day in the case of London babies and on the eighth day in the case of Dublin babies (since the Dublin babies were not as a rule, kept in hospital after the eighth day) have been compared with their birth weights, and the change in weight has been contrasted with the average weight curve given by Holt. The condition has been labelled 'satisfactory' if the progress has been equal to or better than that shown on this curve. In all other cases it has been labelled 'unsatisfactory' or the death of the child has been recorded. Separate tables have been made out for those babies who were fed entirely on the breast for those who were fed entirely artificially and for those fed partly on the breast and partly artificially (mixed fed). Those cases have been excluded in which the mother's malnutrition was due to disease and those in which the baby died or failed to thrive as the result of injury, malformation, or syphilis. Twins also have been excluded. Premature babies have been tabulated separately but they were too few in number to afford data for conclusions of any value.

To take first the full time babies fed entirely on the breast in the London hospitals there were 25 babies of mothers with bad nutrition (A 3) of these 64 per cent. progressed satisfactorily and 36 per cent. failed to thrive. None died. After the mother's nutrition was average (B 3) out of 103 babies 61.1 per cent. flourished, 33 per cent. failed to thrive and 0.9 per cent. died. When the mother's nutrition was good (C 3) out of 251 babies 70.1 per cent. flourished, 29.9 per

cent. failed to thrive and none died. When the cases are classified by the mothers' height and weight ratio alone, of 818 babies born in London of mothers whose height and weight ratio was bad, 65.9 per cent. flourished, 33.7 per cent. failed to thrive, and 0.4 per cent. died. When the mothers' height and weight ratio was average out of 418 babies 62.2 per cent. flourished, 37.5 per cent. failed to thrive, and 0.2 per cent. died. When the height and weight ratio was good, of 836 babies 63.2 per cent. flourished, 36.6 per cent. failed to thrive, and 0.2 per cent. died. The Dublin cases in the classes of bad and average nutrition were so few that conclusions can hardly be drawn from them. Moreover, it is noticeable that mixed breast and artificial feeding seems to be resorted to much more readily in London, when the baby does not seem to be thriving, than in Dublin. Possibly this is partly due to the fact that the London babies stay longer in hospital, so that their progress can be better gauged.

To the figures for the full-time babies fed partly on the breast and partly artificially the same criticisms, of course apply and the Dublin cases are so few as to be almost valueless. There were only 9 full time babies of this kind in London whose mothers' nutrition was bad (A 3). Of these, 33.3 per cent. flourished, 55.5 per cent. failed to thrive, and 11.1 per cent. died. When the mothers' nutrition was average (B 3), out of 66 babies 42.4 per cent. flourished, 57.6 per cent. failed to thrive and none died. When the mothers' nutrition was good (C 3), out of 58 babies 32.8 per cent. flourished, 67.2 per cent. failed to thrive, and none died. Of the London babies, when the mothers' height and weight ratio was bad 30.4 per cent. flourished, 68.4 per cent. failed to thrive, and 1.3 per cent. died out of 237 babies. Similarly, when the height and weight ratio was average the figures are 35.9, 64, and 0 per cent. for 142 babies, and 30.3, 69.4, and 0.3 per cent. when the height and weight ratio was good.

The numbers of the full time babies who were fed entirely artificially were too few to allow of any useful deductions being drawn.

With regard to the infantile death rate before lactation was established the combined figures for London and Dublin give 51 babies whose mothers' nutrition was bad (A 3) with a death rate of 2 per cent., 184 babies of mothers with average nutrition (B 3) with a death rate of 0 and 827 babies of mothers whose nutrition was good (C 3) with a death rate of 0.2 per cent. When the height and weight ratio alone is considered the death rate was approximately the same for all classes.

From the foregoing figures it does not appear that the state of nutrition of the mother at the time of labour and during her pregnancy has any marked influence on the progress of 'mixed fed' and breast fed babies during the first eight or ten days of life. On the other hand the death rate of babies before lactation is established may perhaps be higher when their mothers are really badly nourished. It must be remembered that from the time of labour until their discharge from hospital all the mothers were presumably receiving an ample diet.

Influence of the State of Nutrition of the Mother on her Capability of Suckling

The percentage of breast-fed babies is very much higher in Dublin than in London, and this quite apart from the question of mixed feeding, since the percentage of artificially fed babies—that is of mothers who had no milk at all—is much higher in London than in Dublin. Both in London and in Dublin however the state of the mother's nutrition does seem to have a definite influence on her capability of suckling. Of a total of 3633 babies born in London 73.21 per cent. were breast fed, 24.32 per cent. were mixed fed, and 2.47 per cent. artificially fed. Of 2352 Dublin babies 93.51 per cent. were breast fed, 1.23 per cent. were mixed fed, and 0.25 per cent. artificially fed. These figures exclude babies who died before lactation was established and those who were not breast-fed owing to extraneous causes, such as tubercle, syphilis, sepsis, sore nipples, illegitimacy, &c. Of the 33 babies in London whose mothers' nutrition was bad (A 3) 65.8 per cent. were breast-fed, 23.4 per cent. mixed fed, and 5.3 per cent. artificially fed. The figures have to be compared with 62.7, 36.7, and 0.6 per cent. for 153 babies whose mothers' nutrition was average (B 3), and with 79.5, 17.9, and 2.5 per cent. for 318 babies whose

AN INVESTIGATION INTO SOME OF THE EFFECTS OF THE STATE OF NUTRITION OF THE MOTHER DURING PREGNANCY AND LABOUR ON THE CONDITION OF THE CHILD AT BIRTH AND FOR FIRST FEW DAYS OF LIFE

BY G F DARWALL SMITH, M.A., B.M., B.CH. OXON.,

SURGEON TO OUT PATIENTS SAVAIRIAN FREE HOSPITAL
FOR WOMEN, MARYLEBONE ROAD N.W.

THIS investigation embodies the results of an attempt to estimate some of the effects of the state of a mother's nutrition during pregnancy and at the time of labour on the condition of her child at birth and during the first few days of life, as deduced from statistics obtained from the lying-in hospitals of London and Dublin. The total number of cases investigated was 6162 of which 3721 represented hospital experience in London and 2441 similar experience in Dublin. The method adopted to obtain the statistics was to send out a number of printed cards to the hospitals, on each of which were entered the particulars of one case by the resident medical officer or registrar of the hospital. The cases were not selected in any way. The information thus obtained has been carefully classified and arranged to enable certain conclusions to be drawn if possible.

The most difficult thing in the investigation has been to determine what was the state of a mother's nutrition so that comparisons might be made between different cases. An attempt has been made to arrive at this in three ways.

1. The weights and heights of the patients have been taken soon after they came to the hospitals and before delivery. From these data tables were constructed showing the average weight of a mother for any given height the London and Dublin mothers being treated separately, because it was found that the women of these two cities showed a distinct difference in this respect. A similar height and weight ratio was also taken after excluding all those cases which were shown by criteria 2 and 3, mentioned below, to be in a state of either extremely good or extremely bad nutrition, but the average figures so obtained differed so little from those obtained by the first method that the state of nutrition, so far as this criterion is concerned, has been deduced from the former tables only. Unless there were at least 50 women of any given height from whom the average weight could be computed, the cases were discarded as useless for the purpose of this investigation. The maximum number of women of any given height in London in the series under examination was 580, with a height of 5 ft 2 in. and in Dublin 325 with a height of 5 ft 2 in. The average figures obtained in this way were checked by comparing the weights at labour of 52 women with their weights two months later when involution was presumably complete. In this way the average loss of weight was ascertained, and by adding this amount to the average weight for any given height of a woman in ordinary circumstances as given in Hutchison's tables a result was obtained which agreed very closely with the average figures obtained from the cases weighed at the time of labour. It may be noted in passing that the women whose state of nutrition was good according to criteria 2 and 3 appeared to lose more weight during the puerperium than did those whose state of nutrition was bad according to the same criteria, but the total number investigated in this way was too small to allow any certain conclusion to be drawn on this point.

2. The second way in which an attempt was made to arrive at the state of nutrition of a woman at the time of labour was by getting the medical officer in charge of her to record his impression as to whether this was good average or bad on the card referring to her case.

3. The third way was by having recorded on the cards each woman's own account of the amount of food she had been able to obtain during her pregnancy as being good average or bad.

It was noticeable that a large percentage of those women whose state of nutrition was bad according to criteria 2 and 3

could not be weighed and measured when they arrived at hospital, owing either to the advanced state of labour or to some complication such as accidental hæmorrhage. Cases in which the malnutrition was due to disease have been excluded.

As regards the height and weight ratio those cases have been classed as good whose weight exceeded the average weight of women one inch taller, those cases as bad whose weight fell short of the average weight of women one inch shorter, all other cases have been classed as average. It will be seen from the figures that the number of cases with average nutrition, as tested by this height and weight ratio, is smaller than that of those with either good or bad nutrition. This of course means that many average cases are included in the good and bad classes, and the effect is to understate rather than overstate the conclusions drawn from the good and bad classes, but if the average class had been enlarged by using a different method the number of cases with bad nutrition according to all three criteria would have been so small as to be valueless.

In the light of the above three criteria of the state of a woman's nutrition all the cases available have been divided into classes as follow—

A 3, Cases in which the height and weight ratio the observed state of nutrition, and the nutritional history are all bad.

B 3, Cases in which the height and weight ratio the observed state of nutrition, and the nutritional history are all average.

C 3, Cases in which the height and weight ratio, the observed state of nutrition, and the nutritional history are all good.

A, Cases in which the height and weight ratio is bad.
B, Cases in which the height and weight ratio is average.
C, Cases in which the height and weight ratio is good.
In this classification it will be noticed that most stress is laid on the height and weight ratio.

Influence of the State of Nutrition of the Mother on the Death of the Child during or before Labour

The percentage of dead births in the case of women of bad nutrition (A 3) was 7.7 per cent out of a total of 65 cases. If all the cases suffering from accidental hæmorrhage could have been weighed and measured, the percentage would probably have been still higher. In the class of average nutrition (B 3) the dead births are 1.1 per cent out of a total of 183 cases. In the class of good nutrition (C 3) the percentage is 1.9 for 860 cases. It is noticeable that though the class of lowest nutrition has by far the highest percentage of dead births the class of average nutrition has a lower percentage than the class of good nutrition. This may be due to the increased weight of the babies in the class of good nutrition (*vide infra*). It has to be observed, however, that the last-named class is much larger than the two others. When the height and weight ratio alone is considered the dead births are 2.1 per cent for 2280 cases of bad nutrition, 1.1 per cent for 978 cases of average nutrition and 1.7 per cent for 1824 cases of good nutrition, again a rather higher percentage for those of good than for those of average nutrition.

Influence of the State of Nutrition of the Mother on Prematurity of Labour

In considering these figures it must again be remembered that many mothers with accidental hæmorrhage could not be weighed and measured. Here 11.9 per cent of 59 labours were premature in the class of bad nutrition (A 3). In the class of average nutrition (B 3) 2.7 per cent out of 183 cases. In the class of good nutrition (C 3) 1.3 per cent out of 848 cases. For each group, by the height and weight ratio alone when the mothers' nutrition was had 5.3 per cent were premature out of 2225 cases, when it was average 2 per cent out of 978 cases, and when it was good 2.7 per cent out of 1824 cases.

Influence of the State of Nutrition of the Mother on the Weight of the Birth

For this purpose the birth weight has been classed into three groups: above the average if it exceeded 8 lb, to be of average value if between 6 lb and 8 lb, and to be below the average if below 6 lb. In the class of bad nutrition (A 3) out of 65 babies 10 per cent were above and 14 per cent below

the average weight. In the class of average nutrition (B 3) out of 177 babies 12.4 per cent are above and 11.3 per cent are below. In the class of good nutrition (O 3) 40.1 per cent are above and 3.1 per cent below out of 836 babies. In this case a state of maternal nutrition above the average seems to have a very marked effect in increasing the baby's weight, whereas a bad state of nutrition on the part of the mother has less effect in decreasing it than might have been expected, since the figures for the class of bad nutrition and for that of average nutrition are not very widely removed from one another. When the height and weight ratio alone is taken into consideration, out of 2108 babies of mothers with bad nutrition 17.7 per cent. were above the average weight and 11.8 per cent below, out of 943 babies of mothers with average nutrition 23.4 per cent were above and 8.1 per cent below, and out of 1839 babies of mothers with good nutrition 34.6 per cent were above and 4.1 per cent below.

Influence of the State of Nutrition of the Mother on Post natal Mortality of Infants

Out of 3693 babies born in the London hospitals 2.1 per cent died during the first ten days of life. If, however, those cases are excluded to which the height and weight ratio could not be applied, in which the mothers' malnutrition was due to disease, or in which the baby died as the result of injury, malformation, or syphilis, there remain 3015 babies, of whom 1 per cent died. As contrasted with this, out of 45 babies born in London of mothers with bad nutrition (A 3) 6.66 per cent died, out of 184 babies of mothers whose state of nutrition was average (B 3) 0.5 per cent died, and out of 328 babies of mothers with good nutrition (O 3) 0.3 per cent died. Where the height and weight ratio alone was bad the death rate was 1.3 per cent for 1177 babies, where it was average 0.5 per cent for 589 babies, and where it was good 1 per cent for 1249 babies. In the Dublin hospitals during the first eight days of life the death rate for all the 2439 babies was 2.5 per cent, and for the 1708 cases which could be classified 0.3 per cent. On the other hand the death rate for the 12 Dublin babies of mothers with bad nutrition (A 3) was 8.3 per cent, where the mothers' state of nutrition was average (B 3) none of the 8 babies died, where it was good (O 3) 0.8 per cent of 512 babies died. When the height and weight ratio alone is considered, 0.9 per cent of 934 babies of mothers with bad height and weight ratio died, 0.4 per cent of 241 babies born of mothers with average height and weight ratio, and 0.8 per cent of 533 babies born of mothers with good height and weight ratio.

Influence of the State of Nutrition of the Mother on the Progress of the Child after Birth

For the purpose of ascertaining the progress of the babies after birth their weights on the tenth day in the case of London babies and on the eighth day in the case of Dublin babies (since the Dublin babies were not as a rule kept in hospital after the eighth day) have been compared with their birth weights, and the change in weight has been contrasted with the average weight curve given by Holt. The condition has been labelled "satisfactory" if the progress has been equal to or better than that shown on this curve. In all other cases it has been labelled "unsatisfactory" or the death of the child has been recorded. Separate tables have been made out for those babies who were fed entirely on the breast for those who were fed entirely artificially and for those fed partly on the breast and partly artificially (mixed fed). Those cases have been excluded in which the mothers' malnutrition was due to disease and those in which the baby died or failed to thrive as the result of injury, malformation, or syphilis. Twins also have been excluded. Premature babies have been tabulated separately, but there were too few in number to afford data for conclusions of any value.

To take up the full time babies fed entirely on the breast in the London hospitals there were 25 babies of mothers with bad nutrition (A 3) of these 6 per cent progressed satisfactorily and 75 per cent failed to thrive. None died. When the mothers' nutrition was average (B 3) out of 103 babies 61.1 per cent gained 33 per cent failed to thrive and 0.9 per cent died. When the mothers' nutrition was good (O 3) of 251 babies 70.1 per cent flourished 29.9 per

cent failed to thrive, and none died. When the cases are classified by the mothers' height and weight ratio alone, of 818 babies born in London of mothers whose height and weight ratio was bad, 65.9 per cent flourished, 33.7 per cent failed to thrive, and 0.4 per cent died. When the mothers' height and weight ratio was average out of 418 babies 62.2 per cent flourished, 37.5 per cent failed to thrive, and 0.2 per cent died. When the height and weight ratio was good, of 836 babies 63.2 per cent flourished, 36.6 per cent failed to thrive, and 0.2 per cent died. The Dublin cases in the classes of bad and average nutrition were so few that conclusions can hardly be drawn from them. Moreover, it is noticeable that mixed breast and artificial feeding seems to be resorted to much more readily in London, when the baby does not seem to be thriving, than in Dublin. Possibly this is partly due to the fact that the London babies stay longer in hospital, so that their progress can be better gauged.

To the figures for the full-time babies fed partly on the breast and partly artificially the same criticisms, of course apply, and the Dublin cases are so few as to be almost valueless. There were only 9 full-time babies of this kind in London whose mothers' nutrition was bad (A 3). Of these 33.3 per cent flourished 55.5 per cent failed to thrive, and 11.1 per cent died. When the mothers' nutrition was average (B 3), out of 66 babies 42.4 per cent flourished, 57.6 per cent failed to thrive, and none died. When the mothers' nutrition was good (O 3), out of 58 babies 32.8 per cent flourished, 67.2 per cent failed to thrive, and none died. Of the London babies, when the mothers' height and weight ratio was bad 30.4 per cent flourished, 68.4 per cent failed to thrive, and 1.3 per cent died out of 237 babies. Similarly when the height and weight ratio was average the figures are 35.9, 64 and 0 per cent for 142 babies, and 30.3, 69.4 and 0.3 per cent when the height and weight ratio was good.

The numbers of the full-time babies who were fed entirely artificially were too few to allow of any useful deductions being drawn.

With regard to the infantile death rate before lactation was established the combined figures for London and Dublin give 51 babies whose mothers' nutrition was bad (A 3) with a death rate of 2 per cent, 184 babies of mothers with average nutrition (B 3) with a death rate of 0 and 827 babies of mothers whose nutrition was good (O 3) with a death rate of 0.2 per cent. When the height and weight ratio alone is considered the death rate was approximately the same for all classes.

From the foregoing figures it does not appear that the state of nutrition of the mother at the time of labour and during her pregnancy has any marked influence on the progress of "mixed fed" and breast-fed babies during the first eight or ten days of life. On the other hand, the death rate of babies before lactation is established may perhaps be higher when their mothers are really badly nourished. It must be remembered that from the time of labour until their discharge from hospital all the mothers were presumably receiving an ample diet.

Influence of the State of Nutrition of the Mother on her Capability of Suckling

The percentage of breast-fed babies is very much higher in Dublin than in London, and this quite apart from the question of mixed feeding, since the percentage of artificially fed babies—that is of mothers who had no milk at all—is much higher in London than in Dublin. Both in London and in Dublin however, the state of the mother's nutrition does seem to have a definite influence on her capability of suckling. Of a total of 3538 babies born in London 73.21 per cent were breast fed 24.32 per cent were mixed fed and 2.47 per cent artificially fed. Of 2352 Dublin babies 93.51 per cent were breast fed 1.23 per cent were mixed fed and 0.25 per cent artificially fed. These figures exclude babies who died before lactation was established and those who were not breast-fed owing to extraneous causes, such as tubercle, syphilis, sepsis, sore nipples, inflammation, &c. Of the 33 babies in London whose mothers' nutrition was bad (A 3) 65.8 per cent were breast fed 28.4 per cent mixed fed and 5.3 per cent artificially fed. The figures have to be compared with 62.7, 35.7 and 0.6 per cent for 153 babies whose mothers' nutrition was average (B 3), and with 73.5, 17.9 and 2.5 per cent for 318 babies whose

mothers' nutrition was good (C 3). Of 11 babies in Dublin whose mothers' nutrition was bad (A 3), 72.7 per cent were breast-fed, 18.2 per cent mixed fed, and 9.1 per cent artificially fed. All 7 babies whose mothers' nutrition was average (B 3) were breast-fed. Of 499 babies whose mothers' nutrition was good (C 3), 99.6 per cent were breast-fed, 0.4 per cent mixed fed, and 0 artificially fed.

Influence of the Mother's Capability of Suckling on the Mortality and Progress of the Child after Birth

Out of 2539 full time breast-fed babies in London progress was good in 64 per cent, bad in 36 per cent, and 0.1 per cent died. Similarly, for 2170 Dublin babies the percentages are 56.2, 43.7, and 0.2. For mixed fed babies in London the figures are 81.6—30.4, 70, and 0 per cent, in Dublin 20—15, 80, and 5 per cent. Here, again, is seen the greater readiness to adopt mixed feeding in London than in Dublin. As regards artificially fed babies the figures for London are 81—17.3, 81.5, and 1.2 per cent, for Dublin 16—12.5, 87.5, and 0 per cent. The same effect was evident in the case of premature babies. These figures only express the well known relative advantages of breast feeding, mixed feeding, and artificial feeding.

General Conclusions

The foregoing statistics do not absolutely prove anything, but they seem to suggest the following conclusions:

A state of bad nutrition of the mother at the time of labour due to insufficient food (1) greatly increases the percentage of dead births, (2) greatly increases the percentage of premature births, (3) slightly decreases the average weight of the full time baby at birth, (4) definitely increases the post-natal infantile mortality, (5) has little, if any, effect during the first eight or ten days on the progress of babies who live during that time, and (6) possibly increases the death rate of babies during the first three or four days of life.

A state of good nutrition of the mother at the time of labour, on the other hand, (1) considerably increases the average weight of the full time baby at birth, and (2) increases the percentage of mothers who are able to suckle during the first eight or ten days of the puerperium, quite apart from any effect from the use of an ample diet during this time.

The figures also suggest that on the whole a state of average nutrition of the mother is the most favourable condition.

My best thanks are due to the following medical officers for their help in the collection of these statistics: Dr Sydney Vosper, Dr Rutherford Smith, Dr Weston, Mr J van Soest, and Mr Lionel Colledge, of the British Lying in Hospital, Dr J D Baris of the City of London Lying in Hospital, Dr E S Cooke, Dr M D Hancock, and Dr Ievers, of the Clapham Maternity Hospital, Dr A Lionel Smith, Dr G N B Sebastian, Dr P F Wilson, Dr Dudley Corbett, and Dr W L Pink, of the General Lying in Hospital, Dr Clifford White, and Dr J B Banister, of Queen Charlotte's Hospital, Dr V J McAllister of the Coombe Lying in Hospital, Dublin, and Dr Bethel Solomons and Dr J R Freeland, of the Rotunda Hospital, Dublin. I am much indebted too, to the committees of management of the foregoing hospitals for their kind permission to collect and publish the statistics contained in this investigation.

Grosvenor street W

CENTRAL MIDWIVES BOARD FOR SCOTLAND—The Board was finally constituted on June 27th by order of the Privy Council. The names are the same as those provisionally appointed and announced in our issue of Feb 12th p 366, with the addition of Miss Alice Helen Turnbull and Miss Isabella Lewis Scrimgeour, appointed by the Lord President of the Council.

A FREE CONVALESCENT HOME FOR DELICATE CHILDREN—A convalescent home has been opened at Woodbine, Sidmouth, Devon, for delicate children of naval and military officers and others whose incomes have suffered in the present war. Mrs Cowler, wife of Mr A E Cowler, D Litt, sub-librarian of the Bodleian Library, Oxford. The children must be between the ages of 5 and 10 (or 5 and 8 in the case of boys) and are to stay for a period of four weeks. The house is situated four minutes from the sea and is in charge of a competent matron and nurse. The stay in the home is entirely free of charge and travelling expenses are also defrayed by Mrs Cowler, to whom application should be made at 91 St Aldates, Oxford. A doctor's recommendation should accompany the application.

A REPORT ON THE CASUALTIES FROM THE JUTLAND COAST ACTION RECEIVED AT ROYAL NAVAL HOSPITAL, SOUTH QUEENSFERRY

BY W M ASH, M B, B S LOND.,
TEMPORARY SURGEON, ROYAL NAVY

AND

C P G WAKELEY, M R O S, L R C P LOND.,
TEMPORARY SURGEON, ROYAL NAVY

THIS hospital received 110 badly wounded cases, comprising—shell wounds 62, burns, 42, suffering from the effects of fumes, 4, and from severe shock, 2.

The shell wounds were for the most part multiple, some cases had as many as 20 different lesions, varying from compound fractures to small punctured wounds caused by shell splinters. Almost without exception these were markedly septic on arrival, being less than 48 hours after injury, in spite of the fact that excellent treatment had been administered on board ship. For the greater part the injuries were to limbs. In 3 cases only were the eyes affected, in one the eye was entirely disorganised and septic, enucleation being necessary, another was an incised wound of the sclerotic about half an inch long at a tangent to the corneo sclerotic junction, the third was a shell splinter which had perforated the lower lid and become embedded in the sclerotic coat. On removal it left an ulcer which quickly cleared up. Considering the confined space and the power of the high explosives, it is remarkable that there were so few eye lesions. Of abdominal lesions there were 3 also, 2 of these were suffering from severe wounds elsewhere and survived a short time only, the other man had a perforated wound with local peritonitis, but is doing extremely well at the time of writing.

Fractures were numerous for the greater part compound—in fact, a simple fracture was rare, some patients had as many as three compound fractures. Some, again had one or two inches of bone and large masses of muscle missing, vessels and nerves being exposed. All wounds were very septic. In many cases amputation was the only resort. All our amputations were performed by the circular flapless method. To quote Captain M Fitzmaurice Kelly, R A M C: "It saves life, length of limb, and the risk of secondary hæmorrhage is lessened. It arrests the spread of infection and it is possible where no other method is possible."

The prime object in the treatment of these cases was to combat the sepsis. One of us used esol, the other favoured continuous saline irrigation, and the results up to the present have been equally successful. Both have their advantages. Undoubtedly esol is an excellent application in very early cases—in fact second to none, but when once sepsis has gained a footing continuous saline irrigation seems to meet the requirements, does away with painful dressings and is particularly non-irritating to the injured and exposed peritoneum which is so easily destroyed by the application of antiseptics. Again in these cases secondary hæmorrhage is a very real danger and is much more likely to occur from the frequent application of dressings than with a continuous irrigation, also we consider that much as esol stimulates the growth of granulation tissue, saline stimulates it more. We have observed that the granulation tissue produced by saline does not bleed so profusely on the slightest touch as that produced by esol.

We endeavoured as much as possible to avoid wiring and plating such septic fractures, but in one case this was necessary as in no other way could the fragments be kept away from the popliteal vessels. As we have pointed out before the adequate treatment of sepsis is the primary indication therefore a splint which admitted of easy application as well as effective immobilisation is essential. In cases of fractured humerus we found a Thomas's knee, but in extension met both these requirements, especially as when we had to treat wrists of septic fracture (Cox's) we used around the wrist and ankle joint a very firm band in round splints and immersed in continuous saline irrigation.

I Ref. 5 Jan. 1916 S. 111 p. 57. THE LANCET 22 1916 p. 15

The ordinary wooden splints, such as anterior and posterior splints for the forearm, back splint with foot-piece and side splints for the leg, were quite useless, as all the cases had multiple wounds which required the removal of splints for dressings and would not allow pressure being applied.

As regards burns, these were plentiful and extensive. Since these were due to sudden flashes, it was rare to find a burn of more than a third degree, and equally rare to find them affecting other parts of the body than the hands and face—i.e., the exposed parts. Any burn which is later found to be more than the third degree is generally due to the application of dressings. With removal of dressings a thin superficial layer of granulation tissue epithelium is also removed, if this is continued it is easy to explain why burns become deeper. In our opinion the treatment of burns should be expectant as well as immediate. This treatment is not new fangled, nor is it a war fad. We have used it in civil practice before, chiefly in young children, we used it in the cases from the Dogger Bank action with equally excellent results.

The stages of burns are (a) Stage of shock, (b) stage of sloughing, (c) stage of separation of the slough, (d) stage of scarring. On receipt of a case of burns the immediate treatment is obviously to treat shock. Treatment can be summed up briefly—rest, warmth and morphia, local treatment as for any other septic burn. We open any blebs and apply picric acid, this is both antiseptic and anaesthetic. If possible instead of this we immerse the patient in a warm saline bath especially if the body is affected. If

is the all important factor, this we have already fully dealt with. In the second stage we have to treat sepsis and prevent internal complications, such as bronchitis, diarrhoea and vomiting, duodenal ulcer, &c. In the treatment of sepsis we use chiefly hypertonic saline solution for burns of the extremities, if possible as a bath, as this serves the double purpose of keeping away air and cleansing the wound. To the face if it is impossible to apply a continuous saline douche so as to cover completely the whole

FIG 1

FIG 2

After three weeks' treatment

surface we apply an oil consisting of menthol, 2 gr., eucalyptus oil, 3 min., carron oil to the ounce. We on no account apply a dressing, the oil is applied from a bowl kept at the bedside, from which it is carried to the face on cotton wool. This is applied at frequent intervals the eyes at the same time being irrigated with boric lotion. At least three or four times a day the face is slightly sponged with saline so as to remove any pus which may be present and the greater part of the oil. This ensures that the oil is kept fresh and that no pus is allowed to be imprisoned under scabs, which quickly form if

FIG 4

After three weeks treatment.

shock is very marked we give a continuous saline with a small amount of adrenalin in it. Injection of pituitary lobe or pituitary body or citrate of ergot is equally good but acts for a short time only, strychnine and lobeline we avoid. If picric acid has been used this is continued until shock is completely passed off. Now immediate treatment is a pure place to expectant treatment. We do not expect any treatment naturally proper of the burn. What are the complications? In the first stage shock

this precaution is not taken. If this is done frequently it is the simplest matter and even the slightest hemorrhage is avoided, and above all any little islands of epithelium from which the new skin will be produced are preserved. We have found under this treatment that a burn that has been carefully examined and found to be, say, of the third degree will be no deeper when examined four or five days later.

We do not claim that this treatment is easy and quick, on the other hand, it requires much patience and time but the results amply repay one. At the end of seven to ten days the wound is usually quite clean and the epithelium is very actively growing over the granulating surface. At this stage scarlet B ointments may be used with benefit. By this method we find that we never get the hemorrhage in the third or "suppurating stage" and the fourth or "scarring stage" is seldom seen with burns of the depth of those caused by shell explosion or by the flash of cordite which have been the cause of all the burns we have had to

Moreover, the frequent removal of all the products of inflammation prevents the absorption of toxin or toxins, whatever it may be that causes the internal complications mentioned above. It is thus that our treatment is both immediate and expectant.

Our thanks are due to Fleet-Surgeon P H M Star R N, for his help and for the photographs of burns which he so kindly took for us.

SOME OF THE USES AND ABUSES OF MASSAGE

By E BELLIS CLAYTON, M B, B O CANTAB,

CAPTAIN, R A M C. (T) MEDICAL OFFICER IN CHARGE OF ELECTRICAL AND MASSAGE DEPARTMENT, 4TH LONDON GENERAL HOSPITAL AND KING'S COLLEGE HOSPITAL.

Now that massage is used to such a large extent in the military hospitals it seems necessary to point out some of the dangers of using it indiscriminately in all cases. Thus to give massage continuously for months to a patient with a functional paralysis would tend to keep up the disability rather than cure it, because the massage continually reminds the patient of his condition. On the other hand, where a nerve is injured and the muscles it supplies are paralysed massage is strongly indicated to prevent atrophy and contractures. The following are the treatments which I have found most successful for some of the commoner disabilities that are treated in military hospitals.

1 Functional Paraplegia

In many cases these patients have a considerable amount of rigidity of the back and legs, and this prevents them from sitting up. It is perfectly hopeless to try to cure them with massage. From the start efforts should be made to teach the patient to stand and walk. At first two strong assistants are required to hold him up and usually he cannot move one leg in front of the other. Massage and faradism should be given for the first week or two in addition to the walking exercises, in order to stimulate his muscles and persuade him that he is being helped with treatment. But these must be given up at an early date whether they succeed or not, as they tend after a time to hinder progress. Frequently the patient learns to stand and walk with assistance before the rigidity in his back has passed off sufficiently to allow him to sit up. As soon as possible he should practise walking by himself in some walking machine. Here we have two long parallel bars at such a height and such a width apart that the patient can rest his arms on them comfortably while trying to get his balance. The next stage is to learn to walk in this apparatus without using his arms for support. Finally, when made to walk in the open in all probability he will tend to walk in a circle, but with further training he should learn to walk properly. During all this time he is given exercises on his bed or in a chair for his limbs and trunk, and it is very essential for the masseuse to be always very optimistic and suggest to him in various ways that he is improving daily. It is a great mistake to try to get rid of the rigidity and restore muscular power before getting him on his feet. Massage may be continued for months with this object in view without getting any result.

2 Paralysed Muscles

(a) *Due to nerve injuries*—The paralysed muscles should be treated with stimulating massage and galvanism. Passive movements must be given daily to the joints to prevent stiffness, especially if splints are being worn to relax the paralysed muscles. In addition to this the slightest signs of return of power must be encouraged by giving assisted and active movements to these muscles until they are sufficiently strong for the patient to do exercises by himself. He should then continue with regular exercises until the normal power has returned.

(b) *Functional*—These cases must be treated on the same lines as a functional paraplegia. A little massage and faradism at first to stimulate the muscles and suggest to the patient that he is being treated. If this fails to produce any active movement after a few days the treatment should be discontinued and some other method of treatment. This can be gradually discontinued. This can be gradually discontinued. This can be gradually discontinued.

The success or failure of these cases depends to a large extent on the masseuse herself. She must impress on the patient that the treatment is really effecting a cure. Other functional conditions should be treated on the same lines. Massage if used, is merely to act by suggesting to the patient that he is being treated and recovering.

3 Flabby Heart

This may either occur after a long illness, such as typhoid fever, or may be the "soldier's heart" due to overstrain. These cases respond well to graduated exercises. In the early stage when the patient is still in bed massage, in the form of kneading, to the limbs should be also given. Breathing exercises form an important part of the treatment, and the patient should be taught to breathe slowly and evenly while performing the other movements. In almost every case the pulse rate, if rapid at first, falls during and after the exercises, and it also becomes stronger. The following is an example of a scheme of treatment ordered for a patient who is still confined to bed: (1) Six deep breaths, (2) arm kneading followed by active elbow flexion and extension (six times), (3) six deep breaths, (4) leg kneading followed by active ankle flexion and extension (six times), (5) six deep breaths. This treatment is gradually increased as the patient becomes stronger, body exercises are added, and the massage is discontinued. Finally the patient walks up a certain number of stairs daily under the supervision of the masseuse in addition to the other exercises.

4 Joint Injuries

(a) *After adhesions have been broken down*—The joint is usually swollen, stiff, and painful for the first few days. Passive movements should be commenced the following day to prevent adhesions re-forming. Gentle soothing stroking down the limb, performed by a second masseuse for five minutes before and while the joint is being moved, will often prevent painful contractions of the muscles and so allow of a freer range of movement. No forcing must be allowed. The movements should be very slow and gentle, and the limb well supported so that the muscles can relax.

(b) *Chronic traumatic synovitis*—For this condition exercises are strongly indicated. Even if fluid reaccumulates they should be continued. In addition massage can be given to the joint and the muscles which pass over it, and passive movements until the full range of movement of the joint is established. The exercises should be performed twice a day. Thus for a knee joint one would give knee flexion and extension (1) sitting and (2) standing. The former exercise will be chiefly for the anterior thigh muscles and the latter for the posterior. These exercises can be increased by fixing a weight on the patient's foot. Finally, he should do exercises with his weight on the disabled limb. These exercises should be continued until the patient can hop round the room on his injured leg. These same exercises should be given to all cases in which a cartilage has been removed from the knee before the patient returns to duty. To try to redevelop the thigh muscles with massage only is perfectly hopeless, but massage may be helpful in the earlier stages when the limb aches after very little exercise.

It will be noticed that almost all these treatments end in exercises. I consider this to be very important because muscles always atrophy after an injury in their neighbourhood. But there is another very important reason. If a patient is given massage for a long period and is not made to make an effort himself he is very liable to develop some functional disability. To take a case, a patient who suffered from bad trench feet and had been treated for about six months without being allowed to walk began to develop a talipes varus and a tremor in his legs on active movement. He was made to walk at once and do exercises on his feet to stop this functional disability.

Finally there are the cases which require no massage but simply careful examination to find the cause for the continuation of the disability and then some simple treatment for it.

The following are two cases which were recently admitted to the 4th London General Hospital.

Case 1—The patient was admitted with a fractured hip, at the time of his admission he had been treated for about six months and had been treated for about six months without being allowed to walk. He began to develop a talipes varus and a tremor in his legs on active movement. He was made to walk at once and do exercises on his feet to stop this functional disability.

which the bullet had probably passed. He was given stretching movements for this muscle, and in a week was walking normally

CASE 2—The patient had been shot in the head a year ago. He had suffered from hemiplegia and was sent here for further massage. On examination he was found to have recovered except for slight loss of sense of position. His injury was over the Rolandic fissure. He could not stand or walk, and this was apparently due to slight loss of the sense of position and fear of falling over. He is doing Fränkel's exercises and learning to walk, and already in a week he has shown considerable improvement

These examples should suffice to show that careful discrimination is necessary not only in settling which cases should be given massage, but also in deciding the exact treatment to be given

Denmark Hill S E

AN EXPERIENCE OF GALYL AT ROYAL NAVAL HOSPITAL, CHATHAM

By SHELDON F DUDLEY, M B, B S LOND., & C.,
STAFF SURGEON R.N.

At the Royal Naval Hospital, Chatham, galyl has been substituted for neosalvarsan in the treatment of syphilis and about 1500 injections given. It is compared with neosalvarsan of which drug I have had about a similar experience. The laboratory work and injections on which this article is based have all been done by myself, using the same technique with both drugs thus eliminating personal equation in the results arrived at. 0.4 gm. galyl and 0.9 gm. neosalvarsan, the suggested equivalent doses have been used in all the cases that have been employed to obtain the numbers below. Following the usual routine in the navy which has given excellent results with neosalvarsan, cases were given three intravenous injections of galyl at monthly intervals, with three intramuscular injections of gr 1 of mercury after each dose of the arsenical preparation

With regard to reaction following these two drugs, a comparison was made on the three commonest symptoms—rise of temperature, headache, and vomiting. The graph below contrasts the rise of temperature after a first injection of galyl and neosalvarsan. It is based on 583 injections of galyl and 150 of neosalvarsan. An example will easiest explain the reading of it. 30 per cent of neosalvarsan cases may be expected to develop a temperature between 100°-101° F., whereas a similar rise of temperature is only to be expected in 15.6 per cent. of galyl cases. In the same cases 18 per cent. of those treated with galyl complained of headache while 39.3 per cent of those treated with neosalvarsan complained of the same thing. Vomiting followed in 3.9 per cent of galyl injections and in 21.3 per cent where neosalvarsan was injected. It will be seen that about half the galyl cases are followed by no rise of temperature as marked on a four hourly chart, whereas only a quarter of the neosalvarsan cases escape without any rise of temperature. The lesser toxicity of galyl is also very evident from the few injections that are followed by headache and vomiting as compared with those treated with neosalvarsan

It is my experience that reactions after second and third injections of either drug are far less common than after the first—for example in only 7.3 per cent galyl cases and 14 per cent 914 cases receiving a second intravenous injection did the temperature rise above 99° during the 24 hours following administration. Vomiting and headache are exceptional after injections subsequent to the first

These common febrile reactions are probably caused by the liberation of the endotoxins of the treponema pallidum, otherwise one would expect them to be as frequent after the second and third doses as after the first. Another observation confirms this. 53 cases of "tertiary" syphilis were given a first injection of galyl, 40, or 77.5 per cent, had absolutely no reaction, as against 45.5 per cent all types of syphilis (See graph). In a parallel series of 33

cases treated with neosalvarsan 26, or 68.4 per cent, had no reaction, as against 22.7 per cent of all types of syphilis. This comparative freedom of late syphilis from reaction is presumably due to the fact that late lesions are often single and contain fewer and more resistant spirochetes than are present in the early generalised stages of the disease, hence less endotoxin is liberated by the drugs to cause a reaction

As the Wassermann is essentially a quantitative test, a series of comparative positive and negative results are of little value unless absolutely the same technique with carefully standardised materials is used in both series, the reactions the table shown below is based on fulfil this condition, so are strictly comparative, if of little value otherwise

The table explains itself, except that late secondary syphilis means cases of over a year from infection. "At start" means at the time the treatment started, "one month later," when the case has had one arsenical intravenous injection and 3 grains of mercury, "two months later," when the case has had two arsenical injections and 6 grains of intramuscular mercury

Taking the results as a whole, neosalvarsan seems to have slightly more power in producing a negative Wassermann than galyl. It is not intended to convey the idea that these Wassermans taken during treatment when the patient is saturated with mercury and arsenic are permanent. How far a two years mercurial course may render them so I do not know, anyhow, I have seen many negative Wassermans become positive a month or two after leaving off treatment even after a two years' course of mercury

A point the table shows well is the difficulty of obtaining a negative reaction in the late stages of the disease. In 34 galyl cases in which the reaction was negative at the start of treatment, 7 became positive at the time of the third test, whereas only 1 neosalvarsan case became positive out of 27 negative to start with. Thus, galyl used in this way and in these doses has less power than neosalvarsan to prevent the negative reactions of early cases becoming positive

An attempt was made to compare the action of the drugs on the treponemata in the sores. Twelve syphilitic cases in whose sores treponemata were easily demonstrated under dark ground illumination were given an intravenous injection of galyl, and an equal number of similar cases were given

Drug injected	All types of case				Primary syphilis				Early secondary syphilis				Late secondary syphilis			
	Galyl		914		Galyl		914		Galyl		914		Galyl		914	
	No.	%	No.	%	No.	%	No.	%	No.	%	No.	%	No.	%	No.	%
Total number of cases tested	583		150		101		31		251		110		23		9

neosalvarsan, and the sores were examined for treponemata 6 to 8½ hours after injection. Syphilitic spirochaetes were present in 8 of the galyi cases as against 5 of the neosalvarsan cases. No spirochaetes could be found in any of the 24 sores the morning following injection. I should like to note here that in two cases treated with an intravenous injection of 1 gm ferrivine, the non arsenical preparation recommended by Mr J E R McDonagh, treponemata pallida were easily demonstrated four days after injection. The number of cases is too few to place any reliance on, but they suggest neosalvarsan in the dose used to have a quicker treponemidal action than galyi.

Clinically, in most cases, galyi seems to be almost as valuable as neosalvarsan, ordinary chancres and ulcerative lesions generally clearing up within ten days, but it must be confessed a few cases a month or so after injection still have the remains of a rash and more rarely an unhealed sore, an event which was exceptional in my experience with neosalvarsan. Still, it can exhibit the same dramatic cures as the older drug. The following case is an instance.

A C—, aged 28. Admitted Nov 7th, 1915. Contracted syphilis in May, 1915. He had extensive ulcerations of the tongue and mouth, a rupial rash, some of the lesions 1½ in in diameter, over the whole trunk and limbs, general lymphadenitis, and anal condylomata. He was wasted, anemic, and felt "very ill." After 0.4 gm galyi on Nov 10th the rupial crusts separated in four days, leaving clean granulating surfaces. On the 21st he was discharged from hospital with all lesions healed, a gain in weight of 7 lb, and feeling quite well.

The above observations point to arsenic as the important element in these drugs. The dose 0.4 gm galyi contains just half as much arsenic as 0.9 gm of neosalvarsan, which probably accounts for the slightly less therapeutic effect and lesser toxicity of galyi. Perhaps the lesser toxicity has something to do with its having four benzene rings to the molecule, anyhow the following facts are striking. Inorganic arsenic, any ring, very toxic, one ringed compounds like atoxyl, less toxic, those with two rings as "606" and "914" still less so, and four-ringed galyi probably the least toxic of the lot.

To conclude, it would seem that though excellent results have been obtained with neosalvarsan and mercury with a month's interval between the intravenous injections, this interval is unnecessarily long in the case of galyi. As the dose recommended has only half the arsenic content of neosalvarsan the interval could be halved without any more likelihood of the occurrence of cumulative arsenical poisoning (the prevention of which is the object of long intervals) and I am sure if this was done galyi would be as good an agent in the cure of syphilis as neosalvarsan, in fact, the observations of other users of the drug have practically proved it to be so.

Since writing the above I read Lieutenant-Colonel L W Harrison and Captain O H Mills's interesting communication on ferrivine.¹ Though I only gave two intravenous injections of the drug, before deciding to leave it alone in future the results confirm their observations. One gm ferrivine used as supplied without further dilution was given to each of two cases of primary syphilis. Immediately following injection both men suffered from acute collapse with a livid, sweating skin, scarcely perceptible pulse and respiratory distress. One of the men vomited and had a reactionary temperature of 103° F the same evening. There was, however, no thrombosis at the site of injection. One of these reactions was worse than any immediate result I have seen following over 3000 intravenous injections of neosalvarsan or galyi. (Incidentally eight galyi and three neosalvarsan injections given the same morning with the same apparatus were followed by no unpleasant symptoms.) Spirochaetes were demonstrated in the serum from the sores four days after injection (they were not looked for later than this). Ten days later as no improvement was evident and one of the men had developed a secondary roseola 0.4 gm galyi was given to each case. The penile sores then healed in a week.

The foregoing article is practically an abstract of a paper to be published in the *Journal of the Royal Naval Medical Service* for July 1916 to which anyone who is interested is referred for further detail.

TWO CASES OF PENETRATING WOUNDS OF THE ABDOMEN INVOLVING THE INFERIOR VENA CAVA

BY D C TAYLOR, F.R.O.S.,
TEMPORARY CAPTAIN ROYAL ARMY MEDICAL CORPS

THE two following cases of penetrating wounds of the abdomen, complicated by tearing of the inferior vena cava have recently come under my care.

CASE 1—Private — aged 20, admitted to clearing station 12 hours after being hit by a piece of high explosive shell. Wound of entrance tenth right rib in posterior axillary line, no exit wound. The patient was pale and had marked abdominal pain, tenderness, and rigidity. No vomiting, pulse 100, respirations 23.

Laparotomy was performed. Warm ether vapour, axillary saline. Incision through right rectus, fair amount of free blood in peritoneum. Right lobe of liver penetrated but not bleeding. A single tear 2 inches long in the greater curvature of the stomach, extending on to the anterior wall near the pyloric end, was found and sutured. The stomach was empty and no contents had been extruded. No lesion of bowel was discovered. A small retroperitoneal hematoma was noticed at, and on the right side of, the base of the mesentery of the small gut. A rubber tube was passed to the under surface of the liver and the rest of the incision was closed in layers. Pulse at end of operation 120. The pulse began to fall six hours later and the patient became very blanched, he died eight hours after operation.

Necropsy.—No fresh lesion in gastro-intestinal tract was discovered. There was an enormous retroperitoneal hematoma on the posterior abdominal wall, but little or no fresh bleeding into the peritoneal cavity. An oval hole of about the area of a threepenny piece was found in the anterior wall of the inferior vena cava just below the entry of the right renal vein. Careful search failed to find the missile.

CASE 2—Rifleman —, aged 40 admitted to clearing station three and a half hours after being hit by a fragment from a bomb. Entrance wound one inch to right and half an inch above the umbilicus, no exit. A small tag of omentum was extruded. The patient was pale, pulse 120, abdomen very rigid and tender, had vomited four times.

Laparotomy was performed. Warm ether, axillary saline four hours after injury, incision through right rectus, exposing track of missile, much free blood in peritoneum. Missile had passed through gastro-colic omentum just missing the colon. Two veins were bleeding, ligated. Two large tears in front loop of jejunum were found one at the mesentery border with a small tear of the mesentery, the other at the free border of the bowel immediately opposite. Both tears were sutured. Much bleeding from the posterior abdominal wall on the right side. The intestines were packed back, a hole was found in the posterior peritoneum, just outside the line of the inferior vena cava, and a considerable retro-peritoneal hematoma. The posterior peritoneum was slit up with scissors, when furious bleeding took place from a hole in the anterior wall of the inferior vena cava at and below the entrance of the right renal vein. The tear was longitudinal and three-quarters of an inch long. Bleeding was checked by placing the tip of the left fore finger in the hole in the vessel. Attempts were made to control the bleeding by compressing the vessel above and below, but failed owing to proximity of the renal vein. A pair of artery forceps was placed on the front of the cava just above the wound to produce a clamping effect and then a series of six other artery forceps were applied from above down effectually closing the hole leaving the lumen of the vessel patent but narrowed. The missile was not found. The omentum was then packed around the bodies of the forceps. The abdominal incision was rapidly closed with deep salmon gut sutures taking up all the layers the handles of the artery forceps were left protruding through a gap in the middle of the incision. The pulse at the beginning of the operation was 80 and the blood pressure 140, at the end the pulse was 120 and the blood pressure 80. On the first day after the operation the patient was surprisingly fit pulse 112, vomiting at frequent intervals. Rectal saline given urine normal. On the second day the vomiting stopped. The patient was taking fluids well, pulse 80. The bowels were naturally constipated. On the fourth day warm chloroform and ether mix was given and the stitches above and below the forceps were removed and the muscles sutured. After the sutures were removed a good firm track down to the groin of the forceps. The forceps were then removed one by one and no bleeding took place up to the last pair was removed. This operation was trivial in amount and easily controlled with a pair of

plug Two days later the gauze plug was removed without any further bleeding The patient did not vomit after the second anaesthetic

The patient was evacuated to the base on the tenth day, and a month after the injury I heard that he was doing well in England

I have heard of other cases of wounds involving the inferior vena cava being brought to clearing stations, but I believe they have all ended fatally The second of my two cases shows that it may be possible to save some of these patients by using forcipressure, or possibly suture in cases where the bleeding can be controlled while the suture is inserted The reason that these cases do not bleed to death immediately is that the wounds in the posterior peritoneum and the cava are not, or do not remain, directly superimposed

I am much indebted to Lieutenant-Colonel J W Longstaff, R.A.M.C., for permission to publish these notes, and also to Colonel H M. Rigby, A.M.S., for his advice in the after treatment of the second case

ON THE USE OF TUBERCULIN IN GENERAL PRACTICE

BY J LINTON BOGLE, M.D. EDIN.,

LATE TUBERCULOSIS OFFICER UNDER THE COUNTY COUNCIL (PARTS OF LINDBSEY) LINCOLNSHIRE.

GRANTED the two postulates (1) that tuberculin is a useful remedy in the treatment of tuberculosis, and (2) that the use of tuberculin should not be the exclusive role of the specialist but should belong to the armamentarium of the general practitioner then notes on the main principles of tuberculin administration and hints as to the best practical means of carrying them out should be useful in inducing many medical men in general practice to commence treatment with this valuable remedy in the prevention and cure of the most generally prevalent disease in our country

The best period to commence a course of treatment is in the early stages of the disease at a time when only the family medical attendant is aware of its existence, and when a wise use of the proper remedies means all the difference between a vigorous and useful manhood on the one hand and a wasting and lingering malady on the other, followed too often by an early death My experience as a tuberculosis officer has led me to conclude that amongst medical men generally there is a reluctance to venture on the use of tuberculin based partly on the knowledge that carelessly given, it is a potent cause of evil and partly also on ignorance as to the proper ways and means to begin and to carry out the course of treatment The notes are designedly simple, they are written for the instruction of those who have not hitherto used this method of treatment

General Principles of Tuberculin Administration

Tuberculin if injected into the healthy produces no symptoms whatever but in a tuberculous subject it causes the symptoms of the tuberculin reaction The theoretical explanation of this reaction is that the tuberculous have present in their tissues a specific antibody or lysin, capable of breaking down the tuberculin molecule with the formation of toxins After injection these toxins are carried into the general circulation giving rise to the symptoms of general or focal reaction and are followed by increase in the blood of antituberculous lysin or antibody causing a state of tolerance or increased resistance to the effects of the tuberculin poison

In the administration of tuberculin one of two courses is followed either (1) it is given in small doses repeated at long intervals causing immunisation, or (2) in initial small doses advancing rapidly to large and repeated ones producing immunisation with tolerance The former is the course taken in glarular tuberculosis disease in children and local tuberculosis and the latter in autotoxic disease of internal organs When Koch first discovered the tubercle bacillus and in 1890 his preparation of Old Tuberculin I remember administering the remedy under the advice of a Liverpool doctor The usual mode of treatment at that time was large and increasing doses of tuberculin repeated As a result the remedy quickly killed the patient and the aim of the medical man is to

avoidance of reactions or their production in a very mild degree, as a valuable guide to further treatment

Varieties of Tuberculin

All preparations of tuberculin, whether derived from the human or the bovine bacillus, have similar curative properties They vary, however, in their strength and character The preparations I have generally used are P.T.O., or bovine tuberculin, T.A.F., or tuberculin albumose free, and T, Koch's Old Tuberculin, belonging to the class of soluble extractives Also B.E., bacillus emulsion and P.B.E., bovine bacillus emulsion, belonging to the class of mixed products—i.e., soluble extractions, with the insoluble parts of the tubercle bacillus in addition Their relative strength is approximately as follows, taking T as a standard $T = 1$, $T.A.F. = 1$, $B.E. = \frac{1}{2}$, $P.B.E. = \frac{1}{2}$, $P.T.O. = 1/10$

Preparation of Dilutions

The Record tuberculin syringe consists of a glass cylinder with a capacity of 1 c.c., or 16.9 minims, and is divided into tenths—i.e. divisions of 0.1 c.c. The syringe is filled with tuberculin to the first division the remaining nine divisions are filled with diluent consisting of normal saline with 0.25 per cent of carbolic acid This is the first dilution or Dil A, and consists of 0.1 c.c. of tuberculin in 1 c.c. of dilution, or 1 in 10 Dil B, or the second dilution consists of one division or 1/10 of Dil A, together with 9/10 of diluent, it has 0.01 c.c. of tuberculin in 1 c.c., or 1 in 100 Dil C in like manner has 0.1 c.c. of Dil B to 0.9 c.c. of diluent, and = 0.001 of tuberculin in 1 c.c., or 1 in 1000 Dil D has 0.0001 c.c. of tuberculin in 1 c.c., and Dil E has 0.00001 c.c. in 1 c.c., being respectively 1 in 10,000 and 1 in 100,000 of tuberculin in 1 c.c. of dilution It is convenient to make these dilutions in bottles containing 10 c.c. (Sir A. E. Wright's vaccine bottles) and these bottles have rubber caps through which the needle can be plunged into the dilution without exposing it to the air

Mode of Administration

The usual method is by subcutaneous injection, although it is also given orally, in which case the dose is usually double that given under the skin, but as there is some doubt whether the gastric juices do not change and weaken the action of the tuberculin, the former method is the one in general use It is to be preferred for its quick action, its accurate dosage, and also for the guidance given by the local reaction In non-pulmonary tuberculosis the injection is sometimes made near the site of the diseased gland or joint In oral administration the preparations used are T.R. or B.E., they are given in a wineglassful of cold water an hour before a meal

The Tuberculin Most Suitable for Children

In my experience P.B.E. (the bovine bacillus emulsion) B.E., and, on account of its relative mildness, P.T.O. are the most useful preparations They give a slow and mild reaction and it is here that Wright's system of repeated small doses spread over a long period is so valuable In adults where pulmonary disease is the usual type, it is advisable to begin with T.A.F. or P.T.O. and to follow as a second course, with B.E. The first few doses are carefully watched but usually afterwards they can be rapidly increased until the optimum dose is reached Some very useful guidance can be obtained by observing carefully the symptoms of the tuberculin reaction A local reaction, shown by a thickening or swelling in the tissues with some tenderness or by redness of the skin is a warning that the dose is being increased quickly enough and may soon produce a general reaction A strong general reaction shown by raised temperature, sickness, shivering, headache and malaise and *locally* by signs of crepitation or hæmorrhage in a diseased lung points clearly to the dose being too high and it should be reduced at once

The main guidance in treatment by tuberculin is to be obtained from a regular observance of the temperature (the opinion being left to experts) It should be taken twice daily at 8.30 a.m. and 6 p.m. and recorded upon a chart In all cases of temperature rest is the primary necessity a week in bed is most beneficial especially in the early febrile stages of the disease

Dosage

Dosage of tuberculin varies according to the type of the disease In local tuberculosis in a child an initial dose of 0.0005 1/2000 c.c. of P.T.O. or B.E. and in children

one of 0.00002, 1/50000 c.c., of the same preparations, are fair average commencing doses. In pulmonary phthisis a dose of 0.000002 c.c. to 0.000005 c.c. of P.T.O., B.E. or P.B.E. is sufficient. The sequence of doses is more rapid at first than afterwards. At first every four days, then weekly. After the first few doses the quantity is doubled.

The two following sequences, actually carried out in cases of tuberculous disease in children, are instructive.

1. Boy, aged 10, whose grandfather and two brothers had died from pulmonary tuberculosis, was found to be suffering from tuberculous disease of the glands and bones, having one sinus in the right popliteal space, two sinuses above the right ankle, four openings in the right groin (two discharging freely), two also in the left groin, glands swollen and suppurating on left side of neck. On June 6th, 1914, the initial dose was 0.000001 c.c. P.B.E., and in February, 1915, he was receiving Dil D, 0.00001 c.c. P.B.E., followed at intervals of two to three weeks by Dil D, 0.2, 0.4, 0.6, Dil C, 0.1, 0.2, 0.3, 0.4, 0.45, 0.5, 0.5, 0.6, 0.6, 0.6. His present condition is very satisfactory, all the sinuses are soundly healed, the only remnants of extensive disease from which he suffered being some fibrous scars in the groins and two small fibrous knots on the left and one palpable gland on the right side of the neck. His general health is excellent, with an increase in weight from 4 st 1 lb to 5 st 1 lb.

2. Girl, aged 12. Commencing pulmonary tuberculosis. Had lived in the same house as her uncle, who died of the same disease a few months previously. She reacted to the von Pirquet test, and showed signs of commencing disease of the right lung. During the first few injections local reaction occurred, shown by crepitant râles, altered breath sounds, and fever. Now she has no signs, having lost her cough and other symptoms, and is also gaining in weight. Initial dose, P.T.O. 0.000002, Dil E, 0.2, 0.4, 0.8, D, 0.1, 0.2, 0.3, 0.5 (focal reaction), 0.35, 0.25, 0.35, 0.70, C, 0.1, 0.2, 0.3, 0.4, 0.5, 0.65, 0.75.

Final dose.—The final dose of 0.1 c.c., or the whole c.c. of Dil A, is generally considered the highest safe dose—i.e., 1/10 c.c. of tuberculin and 9/10 diluent, but many medical men do not advance so far, being content with 0.5 A, or 0.75 A. In these higher doses, where the tendency to reaction is more manifest, it is also desirable to lengthen the interval, making it 10 to 14 days in place of a week, and after a few doses either to discontinue treatment for a few months or to inject a dilution of a different preparation of tuberculin of a lower strength. The initial dose of this new course may be of a higher strength than that of the first course on account of the state of tolerance established in the patient.

Errors to be Avoided

It is necessary to remember that in passing from one dilution to another the strength is 10 times greater. Thus a sequence 0.5 D to 0.75 D is an increase of 50 per cent, but from 0.01 to 0.02 is 100 per cent increase, so that on changing to a smaller injection of greater strength the increases should be small. Again, dilutions newly made are stronger than old dilutions and the extractive toxin tuberculin dilutions are less stable than those made from the ground bacillary bodies such as T.R. It is desirable to make fresh dilutions every two or three weeks in the former case and every four or six weeks in the latter or they will lose in strength.

The duration of the course depends upon the patient and the nature of the disease. A nervous patient, tending to high temperatures or hemorrhage, requires smaller doses, and of a slowly acting preparation, such as B.E., and hence the course will be lengthened. In children, too, with glandular disease and in all cases of bone disease the course will be a long one and much patience is required. In pulmonary disease of the ordinary early type the course would last from three to six months with doses at intervals of a week. Then after three months' rest a shorter course of three months with another preparation of tuberculin. While undergoing this special treatment many patients can and do resume their occupations. The two following examples with their sequences of doses are interesting.

(a) Young man aged 21. Pulmonary tuberculosis. Is now at work in a shed (outside) all day at his trade, the local signs having passed away. Once during his illness a dose many times stronger was given by inadvertence with a resulting general reaction and a temperature reaching 104.2 F. Sequence: Dil D P.T.O. 0.5-0.5 C 0.1-0.2, 0.4, 0.55 0.75 B 0.1 0.25 0.5 0.5 0.75 (marked reaction) B 0.1 0.2 0.3 0.4, 0.5, 0.5 0.4 0.5, 0.55 0.75, A 0.1 0.25 0.3 0.4

0.4, 0.5, 0.5, 0.55, 0.6 0.7, 0.75, 0.75, 0.8, reaction to 99.5 F. Change to P.B.E. Dil C, 0.1 0.15 0.25, 0.35, 0.5 0.75, B 0.1 0.15, 0.2, 0.3, 0.35, 0.35, P.B.E., 0.3, c.c. (here the error occurred) Dil B, 0.35, 0.5, 0.75, A, 0.1 0.15, reaction to 99.2° F. Once. This second course is now closed.

(b) Young man aged 27, shop assistant. Cavity in right apex, with consolidation of upper lobe of right lung and hæmoptysis. Had been in sanatorium for three months. The commencing dose was Dil D, 0.00001 c.c. of P.B.E., D, 0.1, 0.2, 0.4 0.7, C, 0.1, 0.2, 0.35, 0.5, 0.75, B 0.1 0.2, 0.3, 0.45, 0.7, A, 0.1, slight hæmoptysis, rest from business for two weeks, one weekly injection omitted then followed by A, 0.15, 0.15, 0.25, 0.2. He is working daily at his business and has had no higher temperature than 98.6° F. since the first injection. Pulmonary symptoms quiescent and disease gradually drying up.

Tests for Tuberculosis

Von Pirquet's test (cutaneous) is the most readily applied the most satisfactory in its results, and the one generally used. This test is carried out as follows. The points of the scarifier having been sterilised by heating red hot in the flame of the spirit lamp, a few scratches are made, as a control, upon the outer extensor surface of the arm or forearm, which has previously been carefully cleaned and at a spot a few inches above, a drop of T. (Old Tuberculin) is, with the syringe, dropped upon the skin. The scarifier makes a few cross scratches under the tuberculin until a faint redness is perceptible. Tuberculin can be used pure or diluted, the rule being that the lower the strength used, to cause a reaction, the more active the disease. In 36 or 48 hours afterwards a note is taken of the temperature and of the condition of the punctured spots. If the result be positive the temperature may rise and the tuberculin spot become red and inflamed, with perhaps even a vesicular areola.

Contra indications to the Use of Tuberculin

Although experts, with their knowledge and wide experience, may be able to use tuberculin in most cases of tuberculosis with benefit and without injury, there are cases in which the general practitioner would do well to avoid the use of this remedy. In mixed infections catarrhal or bronchial or complicated by disease of the heart or kidneys, in rapidly advancing or extensive disease, in cases of high fever and quick pulse, in anaemia associated with little power of resistance, in those in whom there is a strong hæmorrhagic tendency, and in cases of infantile tuberculosis, tuberculin as a rule does no good.

Although I have confined my remarks almost exclusively to tuberculin administration in treatment it must never be lost sight of that unless a patient understands the advantage of life in the open air with abundance of light and sunshine, rest, healthy surroundings, the avoidance of excitement and the value of good and nourishing food with cod liver oil and other food tonics tuberculin alone can do very little. It is only in conjunction with a rational general treatment that the striking results of the special treatment are manifest. It is here that residence in a sanatorium does so much. It teaches the tuberculous patient how to live.

"Festina lente" is the golden rule in tuberculin administration, as experiments have shown that even such a minute dose as 1/1,000,000 c.c. of tuberculin can raise the opsonic index from 0.70 to 1.3 although not the slightest clinical symptoms of change were present.

A word, in conclusion as to the cost of the apparatus required. A good tuberculin syringe with two steel needles can be obtained for 9s. 6d. Tuberculin in its different preparations varies in price from 1s. to 3s. a bottle containing 1 c.c. The scarifier costs only a few shillings and the adjuncts are easily obtained at any chemist's. Altogether a very simple outfit.

Alexandra Rosa Day was observed at Portsmouth on June 24th when £925—a record sum—were collected on behalf of the Royal Hospital and the Free and Far Hospitals.

CLERICAL MEDICAL AND GENERAL LIFE ASSURANCE SOCIETY.—The year has certainly had no deteriorating effect on the business of this well known society. The new year has seen for the first time since ended June 30th was £731,472 being an increase of £17,700 over that of last year with new premiums of £1,722,000 and an increase of £1953. The amount of the claims was £500,341, being a decrease of £3,719 as compared with the previous year. Included in this amount is £1,154 paid for war claims.

Reviews and Notices of Books.

Burdett's Hospitals and Charities, 1916

By Sir HENRY BURDETT, K.C.B., K.C.V.O. London
The Scientific Press, Limited. Price 10s 6d net

THIS is an authoritative guide to British, American, and Colonial hospitals and asylums, medical schools and colleges, nursing and convalescent institutions, consumption sanatoria, and other institutions of a similar character, giving a review of their position and requirements, management, revenue, and cost of maintenance, and there is no reference book more convenient and useful than "Burdett's Hospitals and Charities." The present edition is on the lines of its predecessors, among the additional matter being a list of London institutions affording facilities for post-graduate work and a list of territorial hospitals. The great hospital funds of London, the institutions for the care of the blind, deaf, and dumb, orphanages, missions, nursing and convalescent institutions are all described, while there are chapters on hospital finance and hospital charity generally. The magnitude of the interests touched upon can be realised by the statement that in the year 1914 the 1978 charities of which particulars are forthcoming had an income from all sources of £12,907,000, or a decrease of £651,000 from the income for 1913. The expenditure in 1914 was £12,144,000 as compared with £12,280,753 in 1913. The expenditure on the management of hospitals will, of course, be enormously increased as a consequence of the war, while accommodation for the wounded has multiplied throughout the country, representing 100,000 additional beds. Sir Henry Burdett pays a well-deserved tribute to the way in which the voluntary hospitals have responded to the demands made upon them in spite of the heavy financial drain on institutional resources. It is interesting to note that the Norfolk and Norwich Hospital has obtained a new source of revenue by an appeal in the form of 200 written letters, costing one sovereign, for contributions of £5 per month for each of the soldiers' beds. The response produced £5721. The beds are maintained by individuals and groups of persons of all classes domestic servants contributing no less than £152. It is hoped that this system will produce a steady revenue after the war.

In his preface Sir Henry Burdett refers to the fact that 50 years of continuous work for the voluntary hospitals of this country will be completed should he live until August, 1918, by which time he will have passed the allotted span of threescore years and ten. For several years in succession he has appealed for someone to take up and continue his task as editor, and it is to be regretted that there has been no response to the appeal. We hope that Sir Henry Burdett will be spared to edit for a long time yet a book of the utmost value to everyone interested in hospital charities but it would be a great loss to the hospital world if from any cause the book which has been regularly issued for 27 years should fail to make its appearance.

Publié sous la direction de A. LE DENTU et PIERRE DELPECH. *Fractures*. Vol. I. *Fractures en Général*. *Fractures du Membre supérieur*. Par JEAN TANTON, Médecin major de l'Armée. Professeur agrégé du Val de Grâce. Avec 470 figures dans le texte. Paris J. B. Baillière et Fils 1915. Pp. 860. Price 20 francs.

THIS fasciculus of an important treatise on surgery has appeared in spite of the war and it is of special value when innumerable fractures present themselves to all those surgeons who are concerned with the treatment of the wounded. A glance at the volume is sufficient to show the thorough way in which the subject of fractures has been treated. Fractures of the skull of the vertebral column and of the thorax have been excluded as they have been treated in other fasciculi of this system of surgery while the author has been unable to include in this volume more than the general subject of fractures and the fractures of the upper limb. The fractures of the lower limb and of the pelvis will form the subject of another volume. The great increase in our knowledge of fractures has

been undoubtedly due to the introduction of the X rays, for thus we have been enabled to gain exact knowledge of the pathology of the living, and the author has appreciated to the full the value of skiagrams, for he has included in his work a large number. He is, however, fully alive to the erroneous deductions which the untrained may draw from X ray photographs, and he shows us illustrations exemplifying this fact.

It is needless to criticise in detail such a work as this when we are able to draw attention to the completeness and exactitude with which the author has dealt with the whole subject. We cannot give a better example of his thoroughness than his treatment of fracture of the base of the first metacarpal bone, for he recognises three, or rather four forms of this fracture, and each of these varieties is illustrated with photographs. The sections dealing with the treatment of the various fractures are good, the illustrations are abundant and apposite.

We have not met a more scholarly treatise on fractures, and we look forward with interest to the appearance of the next volume.

The Origin and Nature of the Emotions *Miscellaneous Papers*

By GEORGE W. ORLE, M.D., Professor of Surgery, School of Medicine, Western Reserve University, Cleveland. Edited by AMY F. ROWLAND, B.S. London and Philadelphia W. B. Saunders Company 1915. Pp. 240. Price 13s net.

Dr Orle's work on shock, anæsthesia, and kindred topics is already well known in this country. The present volume contains various papers that bear more or less on his previous contributions, they serve also as a preface to certain monographs which we are told are in preparation. It is not practicable to give an analysis of all the eight essays comprising this volume, they deal with such diverse subjects as the relation between the physical state of the brain cells and brain functions, alkaliescence, acidity and anæsthesia, pain, laughter and crying, a mechanistic view of psychology, a mechanistic theory of disease—to name but some of them. We may refer more particularly to those which have a bearing on the title of the book.

Briefly, it may be stated that the author has determined by laboratory researches that such emotions as fear and anger produce the same histological changes in the brain as physical trauma. Inasmuch as the phylogenetic origin of fear is injury it follows that injury and fear cause the same phenomena. In their quality and in their expression psychic shock and physical shock are the same. Dr Orle has made a patient investigation of the cells of the cortex in human cases of exhausting diseases in various animals completely exhausted by running and fighting by rage and fear by physical injury, and by the injection of strychnine, and in every instance he has been able to demonstrate that the loss of vitality—in other words the loss of the normal power to convert potential into kinetic energy—is accompanied by physical changes in the brain cells. He concludes that these changes are "work" changes. But further changes were also found in the adrenals and in the liver again in every instance. Dr Orle regards these three organs as constituting what he calls the "kinetic system." Linked to it is the thyroid gland. "When the kinetic system is driven at an overwhelming rate of speed, as by severe physical injury by intense emotional excitation by perforation of the intestines, by the sudden onset of an infectious disease by an overdose of strychnine by a Marathon race, by a grilling fight by anaphylaxis the result of these acute overwhelming activations of the kinetic system is clinically designated shock and according to the cause is called traumatic shock toxic shock anaphylactic shock drug shock, &c." In this way the author endeavours to harmonise the pathological changes in these organs in disease with the occurrence of the same changes as the result of emotional strain. Conversely any agency that can sufficiently inspire faith or dispel worry will inhibit the action of emotion on these organs. They can be and are physically damaged by fear—they can be protected and strengthened in their function by suitable psychical stimuli.

We commend to the thoughtful reader these essays on the fascinating subject of psychical and physical interaction.

one of 0 00002, 1/50000 c.c., of the same preparations, are fair average commencing doses. In pulmonary phthisis a dose of 0 000002 c.c. to 0 000005 c.c. of P.T.O., B.E., or P.B.E. is sufficient. The sequence of doses is more rapid at first than afterwards. At first every four days, then weekly. After the first few doses the quantity is doubled.

The two following sequences, actually carried out in cases of tuberculous disease in children, are instructive.

1. Boy, aged 10, whose grandfather and two brothers had died from pulmonary tuberculosis, was found to be suffering from tuberculous disease of the glands and bones, having one sinus in the right popliteal space, two sinuses above the right ankle, four openings in the right groin (two discharging freely), two also in the left groin glands swollen and suppurating on left side of neck. On June 6th, 1914, the initial dose was 0 000001 c.c. P.B.E., and in February, 1915, he was receiving Dil D, 0 00001 c.c. P.B.E., followed at intervals of two to three weeks by Dil D, 0 2, 0 4, 0 6, Dil C, 0 1, 0 2, 0 3, 0 4 0 45, 0 5 0 5, 0 6, 0 6, 0 6, 0 6. His present condition is very satisfactory, all the sinuses are soundly healed, the only remnants of extensive disease from which he suffered being some fibrous scars in the groins and two small fibrous knots on the left and one palpable gland on the right side of the neck. His general health is excellent, with an increase in weight from 4 st 1 lb to 5 st 1 lb.

2. Girl, aged 12. Commencing pulmonary tuberculosis. Had lived in the same house as her uncle, who died of the same disease a few months previously. She reacted to the von Pirquet test, and showed signs of commencing disease of the right lung. During the first few injections focal reaction occurred, shown by crepitant râles, altered breath sounds, and fever. Now she has no signs, having lost her cough and other symptoms, and is also gaining in weight. Initial dose, P.T.O. 0 000002 Dil E, 0 2, 0 4, 0 8, D, 0 1, 0 2, 0 3, 0 5 (focal reaction), 0 35, 0 25, 0 35, 0 70, C, 0 1, 0 2, 0 3, 0 4, 0 5, 0 65, 0 75.

Final dose.—The final dose of 0 1 c.c., or the whole c.c. of Dil. A, is generally considered the highest safe dose—i.e., 1/10 c.c. of tuberculin and 9/10 diluent, but many medical men do not advance so far, being content with 0 5 A, or 0 75 A. In these higher doses, where the tendency to reaction is more manifest, it is also desirable to lengthen the interval, making it 10 to 14 days in place of a week, and after a few doses either to discontinue treatment for a few months or to inject a dilution of a different preparation of tuberculin of a lower strength. The initial dose of this new course may be of a higher strength than that of the first course on account of the state of tolerance established in the patient.

Errors to be Avoided

It is necessary to remember that in passing from one dilution to another the strength is 10 times greater. Thus a sequence 0 5 D to 0 75 D is an increase of 50 per cent but from 0 0 1 to 0 0 2 is 100 per cent increase, so that on changing to a smaller injection of greater strength the increases should be small. Again, dilutions newly made are stronger than old dilutions, and the extractive toxin tuberculin dilutions are less stable than those made from the ground bacillary bodies such as T.R. It is desirable to make fresh dilutions every two or three weeks in the former case, and every four or six weeks in the latter or they will lose in strength.

The duration of the course depends upon the patient and the nature of the disease. A nervous patient, tending to high temperatures or hemorrhage, requires smaller doses, and of a slowly acting preparation, such as B.E., and hence the course will be lengthened. In children, too, with glandular disease and in all cases of bone disease the course will be a long one and much patience is required. In pulmonary disease of the ordinary early type the course would last from three to six months with doses at intervals of a week. Then, after three months' rest a shorter course of three months with another preparation of tuberculin. While undergoing this special treatment many patients can and do resume their occupations. The two following examples with their sequences of doses are interesting—

(a) Young man aged 21. Pulmonary tuberculosis. Is now out work in a shed (outside) all day at his trade, the local signs having passed away. Once during my absence a dose many times stronger was given by inadvertence with a resulting general reaction and a temperature reaching 101 2 F. Sequence Dil D P.T.O. 0 5 0 5 C 0 1 0 2 0 4 0 55 0 75 B 0 1 0 25 0 5 0 5 0 75 (marked reaction) R 0 1 0 55 0 75 A 0 1 0 25 0 3 0 4, 0 2 0 3 0 4 0 5 0 5 0 4 0 5 0 55, 0 75, A 0 1 0 25 0 3 0 4,

0 4, 0 5, 0 5 0 55, 0 6 0 7, 0 75, 0 75, 0 8, reaction to 93 F. Change to P.B.E. Dil C, 0 1 0 15, 0 25, 0 35, 0 5, 0 75 B, 0 1 0 15, 0 2, 0 3, 0 35, 0 35, P.B.E., 0 35 c.c. (here the error occurred) Dil B, 0 35, 0 5, 0 75, A, 0 1 0 15, reaction to 99 2° F. Once. This second course is now closed.

(b) Young man aged 27, shop assistant. Cavity in right apex, with consolidation of upper lobe of right lung and hæmoptysis. Had been in sanatorium for three months. The commencing dose was Dil D, 0 00001 c.c. of P.B.E., D, 0 1, 0 2, 0 4 0 7, C, 0 1, 0 2, 0 35, 0 5, 0 75, B, 0 1, 0 2, 0 3, 0 45, 0 7, A, 0 1, slight hæmoptysis, rest from business for two weeks, one weekly injection omitted then followed by A 0 15, 0 15, 0 25, 0 2. He is working daily at his business and has had no higher temperature than 98 6° F. since the first injection. Pulmonary symptoms quiescent and disease gradually drying up.

Tests for Tuberculosis

Von Pirquet's test (cutaneous) is the most readily applied, the most satisfactory in its results, and the one generally used. This test is carried out as follows. The points of the scarifier having been sterilised by heating red hot in the flame of the spirit lamp, a few scratches are made, as a control, upon the outer extensor surface of the arm or forearm, which has previously been carefully cleansed and at a spot a few inches above, a drop of T. (Old Tuberculin) is, with the syringe, dropped upon the skin. The scarifier makes a few cross scratches under the tuberculin until a faint redness is perceptible. Tuberculin can be used pure or diluted, the rule being that the lower the strength used to cause a reaction, the more active the disease. In 36 or 48 hours afterwards a note is taken of the temperature and of the condition of the punctured spots. If the result be positive the temperature may rise and the tuberculin spot become red and inflamed, with perhaps even a vesicular areola.

Contra indications to the Use of Tuberculin

Although experts, with their knowledge and wide experience may be able to use tuberculin in most cases of tuberculosis with benefit and without injury, there are cases in which the general practitioner would do well to avoid the use of this remedy. In mixed infections, catarrhal or bronchial or complicated by disease of the heart or kidneys, in rapidly advancing or extensive disease, in cases of high fever and quick pulse, in anæmia associated with little power of resistance, in those in whom there is a strong hæmorrhagic tendency, and in cases of infantile tuberculosis tuberculin as a rule does no good.

Although I have confined my remarks almost exclusively to tuberculin administration in treatment, it must never be lost sight of that unless a patient understands the advantage of life in the open air with abundance of light and sunshine, rest, healthy surroundings, the avoidance of excitement and the value of good and nourishing food, with cod liver oil and other food tonics tuberculin alone can do very little. It is only in conjunction with a rational general treatment that the striking results of the special treatment are manifest. It is here that residence in a sanatorium does so much. It teaches the tuberculous patient how to live.

'Festina lente' is the golden rule in tuberculin administration as experiments have shown that even such a minute dose as 1/1 000 000 c.c. of tuberculin can raise the opsonic index from 0 70 to 1 3 although not the slightest clinical symptoms of change were present.

A word, in conclusion as to the cost of the apparatus required. A good tuberculin syringe with two steel needles can be obtained for 9s. 6d. Tuberculin in its different preparations varies in price from 1s. to 3s. a bottle containing 1 c.c. The scarifier costs only a few shillings and the adjuncts are easily obtained at any chemist's. Altogether a very simple outlay.

Alexandra Rosa Day was observed at Portsmouth on June 24th, when £925—a record sum—were collected on behalf of the Royal Hospital and the Eye and Ear Hospital.

CERICAL, MEDICAL, AND GENERAL LIFE ASSURANCE SOCIETY.—The war has certainly had no deteriorating effect on the business of this well-known society. The new net life business for the financial year ended June 30th was £737 472 being an increase of £1 150 over that of the year with new premiums of £25 732 and an increase of £1953. The amount of the claims was £300 511 being a decrease of £45 710 as compared with the previous year. Included in this amount is £2 145 paid for war claims.

Reviews and Notices of Books.

Burdett's Hospitals and Charities, 1916

By Sir HENRY BURDETT, K.C.B., K.C.V.O. London
The Scientific Press, Limited. Price 10s. 6d. net

THIS is an authoritative guide to British, American, and Colonial hospitals and asylums, medical schools and colleges, nursing and convalescent institutions, consumption sanatoria, and other institutions of a similar character, giving a review of their position and requirements, management, revenue, and cost of maintenance, and there is no reference book more convenient and useful than "Burdett's Hospitals and Charities." The present edition is on the lines of its predecessors, among the additional matter being a list of London institutions affording facilities for post-graduate work and a list of territorial hospitals. The great hospital funds of London, the institutions for the care of the blind, deaf, and dumb, orphanages, missions, nursing and convalescent institutions are all described, while there are chapters on hospital finance and hospital charity generally. The magnitude of the interests touched upon can be realised by the statement that in the year 1914 the 1978 charities of which particulars are forthcoming had an income from all sources of £12,907,000, or a decrease of £651,000 from the income for 1913. The expenditure in 1914 was £12,144,000 as compared with £12,280,753 in 1913. The expenditure on the management of hospitals will, of course, be enormously increased as a consequence of the war, while accommodation for the wounded has multiplied throughout the country, representing 100,000 additional beds. Sir Henry Burdett pays a well-deserved tribute to the way in which the voluntary hospitals have responded to the demands made upon them in spite of the heavy financial drain on institutional resources. It is interesting to note that the Norfolk and Norwich Hospital has obtained a new source of revenue by an appeal in the form of 200 written letters, costing one sovereign, for contributions of £5 per month for each of the soldiers' beds. The response produced £5721. The beds are maintained by individuals and groups of persons of all classes, domestic servants contributing no less than £152. It is hoped that this system will produce a steady revenue after the war.

In his preface Sir Henry Burdett refers to the fact that 50 years of continuous work for the voluntary hospitals of this country will be completed should he live until August, 1918, by which time he will have passed the allotted span of threescore years and ten. For several years in succession he has appealed for someone to take up and continue his task as editor, and it is to be regretted that there has been no response to the appeal. We hope that Sir Henry Burdett will be spared to edit for a long time yet a book of the utmost value to everyone interested in hospital charities but it would be a great loss to the hospital world if from any cause the book which has been regularly issued for 27 years should fail to make its appearance.

Nouveau Traité de Chirurgie

Publié sous la direction de A. LE DENTU et PIERRE DUBOIS. *Fractures Vol. I. Fractures en Général. Fractures du Membre supérieur.* Par JEAN TASTON. (Médecin major de l'Armée. Professeur agrégé du Val de Grâce. Avec 470 figures dans le texte. Paris. J. B. Baillière et Fils. 1915. Pp. 860. Price 20 francs.)

THIS fasciculus of an important treatise on surgery has appeared in spite of the war, and it is of special value when innumerable fractures present themselves to all those surgeons who are concerned with the treatment of the wounded. A glance at the volume is sufficient to show the thorough way in which the subject of fractures has been treated. Fractures of the skull of the vertebral column and of the thorax have been exhaustively treated, as they are in other fasciculi of this system of surgery, while the author has been unable to include in this volume more than the general subject of fractures of the bones of the upper limb. The fractures of the lower limb and of the pelvis will form the subject of another volume. The treatment of fractures has been dealt with in our knowledge of fractures has

been undoubtedly due to the introduction of the X rays, for thus we have been enabled to gain exact knowledge of the pathology of the living, and the author has appreciated to the full the value of skiagrams, for he has included in his work a large number. He is, however, fully alive to the erroneous deductions which the untrained may draw from X ray photographs, and he shows us illustrations exemplifying this fact.

It is needless to criticise in detail such a work as this when we are able to draw attention to the completeness and exactitude with which the author has dealt with the whole subject. We cannot give a better example of his thoroughness than his treatment of fracture of the base of the first metacarpal bone, for he recognises three, or rather four forms of this fracture, and each of these varieties is illustrated with photographs. The sections dealing with the treatment of the various fractures are good, the illustrations are abundant and apposite.

We have not met a more scholarly treatise on fractures, and we look forward with interest to the appearance of the next volume.

The Origin and Nature of the Emotions. Miscellaneous Papers

By GEORGE W. CRILE, M.D., Professor of Surgery, School of Medicine, Western Reserve University, Cleveland. Edited by AMY F. ROWLAND, B.S. London and Philadelphia. W. B. Saunders Company. 1915. Pp. 240. Price 13s. net.

Dr Crile's work on shock, anoci association, and kindred topics is already well known in this country. The present volume contains various papers that bear more or less on his previous contributions, they serve also as a preface to certain monographs which we are told are in preparation. It is not practicable to give an analysis of all the eight essays comprising this volume, they deal with such diverse subjects as the relation between the physical state of the brain-cells and brain functions, alkaliescence acidity and anaesthesia pain, laughter and crying, a mechanistic view of psychology, a mechanistic theory of disease—to name but some of them. We may refer more particularly to those which have a bearing on the title of the book.

Briefly, it may be stated that the author has determined by laboratory researches that such emotions as fear and anger produce the same histological changes in the brain as physical trauma. Inasmuch as the phylogenetic origin of fear is injury it follows that injury and fear cause the same phenomena. In their quality and in their expression, psychic shock and physical shock are the same. Dr Crile has made a patient investigation of the cells of the cortex in human cases of exhausting diseases in various animals completely exhausted by running and fighting, by rage and fear by physical injury, and by the injection of strychnine, and in every instance he has been able to demonstrate that the loss of vitality—in other words the loss of the normal power to convert potential into kinetic energy—is accompanied by physical changes in the brain cells. He concludes that these changes are "work" changes. But further, changes were also found in the adrenals and in the liver again in every instance. Dr Crile regards these three organs as constituting what he calls the "kinetic system." Linked to it is the thyroid gland. "When the kinetic system is driven at an overwhelming rate of speed, as by severe physical injury by intense emotional excitation by perforation of the intestines, by the sudden onset of an infectious disease by an overdose of strychnine by a Marathon race, by a grilling fight by anaphylaxis the result of these acute overwhelming activations of the kinetic system is clinically designated shock and according to the cause is called traumatic shock toxic shock anaphylactic shock drug shock, &c." In this way the author endeavours to harmonise the pathological changes in these organs in disease with the occurrence of the same changes as the result of emotional strain. Conversely any agency that can sufficiently inspire faith or dispel worry will inhibit the action of emotion on these organs. They can be and are physically damaged by fear—they can be protected and strengthened in their function by suitable psychological stimuli.

We commend to the thoughtful reader these essays on the fascinating subject of psychological and physical interaction.

JOURNALS

Quarterly Journal of Experimental Physiology Editors E A SCHÄFER, W D HALLIBURTON, C S SHERRINGTON, E H STABLING, and A D WALKER Vol IX, No 4 London Charles Griffin and Co, Limited 1916 Pp 281-401 Price 7s 6d.—On the Regeneration of the Cervical Sympathetic After Section, by R Tsukaguchi The experiments were made on two dogs and a number of adult cats In the dogs, about six months after cutting out a portion of the vagus and sympathetic trunks the paralytic symptoms affecting the eye and other parts are not entirely recovered from There is no restoration of the inhibitory action of the vagus on the heart nor of its motor effects upon the œsophagus and stomach The histological observations indicate that the regeneration of the sympathetic has been accomplished not by its own fibres alone, but to a large extent by others of vagus origin In cats, the regenerating fibres of the cut sympathetic first reach the superior cervical ganglion between three and four weeks after section and begin to function about six weeks after section—Notes on the Functional Regeneration of the Out Cervical Sympathetic and Vagus By E A Schäfer and H O. Feiss—Even 10 to 12 months after excision of a portion of the cervical vagus and sympathetic, there are still differences observable in the physiological conditions of the parts supplied by the sympathetic as compared with the normal side Stimulation of the peripheral (upper) end of the cut and regenerated sympathetic evokes the usual effects after such periods, but a stronger stimulus is required than the normal side A decidedly stronger stimulation of the lower stump is required to elicit the effects of sympathetic excitation in the eye, results which are easily elicited by stimulation of the upper stump This appears to indicate that vagal fibres have been largely instrumental in effecting the regeneration of the peripheral sympathetic No sign of physiological recovery of the peripheral cut vagus, one dog, five cats could be obtained after intervals of from 10 to 13 months—The Influence of Muscle Extract on Muscle Contraction, by S Takayasu Saline extract of muscle affects the contraction of the frog sartorius in much the same way as a saline extract which contains excess of potassium The deleterious effects produced by muscle extract in the contraction are due to potassium These effects can be antagonised by a small addition of calcium chloride to the extract—The Influence of Adrenalin on the Contraction of Skeletal Muscle, by S Takayasu Solutions of adrenalin 1 in 1 000 000 show no distinct effect on the frog sartorius Immersion in solutions 1 in 500 000 or 1 in 5000 diminishes the contractile power, the effect being most marked on the height and duration of the curve, while the latency is little affected Muscle poisoned by immersion in solutions of adrenalin rapidly recovers on being transferred to normal Ringer Adrenalin muscular contractions are not fatigue contractions, and are unlike those produced under the influence of veratrine, although they resemble to some extent those obtained under the influence of excess of potassium salts—Experimental Researches on Sensory Localisations in the Cerebral Cortex by J G Dusser de Barenne Extirpation and not electrical stimulation methods have been the more prolific in advancing our knowledge of sensory cortical localisation The author claims that his method of the local application of strychnine to the exposed uninjured cortex is a great advance on the extirpation method Strychnine produces symptoms of excitation in the sensory sphere Some of the author's results in his experiments on cats are as follows Application of strychnine to a local "active zone" of the cortex causes constant and typical symptoms of excitation but if applied outside this zone there is no like disturbance The sensory disturbance produced affects both cutaneous and deep sensibility the disturbances in the latter manifesting themselves in an abnormal hyperesthesia to pinching and pressure of the bones tendons and muscles As to the sensory functions of the skin both sides of the body are represented in the cortex of one hemisphere but on the opposite side most The author gives a minute analysis of the localisation of the sensory areas for head and limbs The lobus frontalis has no sensory functions in the cat The paper is illustrated by a large number of figures of the brain and one plate—The Effects of Thyroidectomy and Thyroid Feeding upon the Adrenalin Content of the Suprarenals by P T Herring Complete thyroidectomy has little, if any permanent effect upon the adrenalin content of the suprarenals of the rabbit—an animal in which no characteristic

symptoms follow removal of the thyroid In cats the adrenalin content of the suprarenals is diminished in direct proportion to the severity of the symptoms induced by removal of the thyroids

The Military Surgeon—The last issue has a special value just now, for the reports from the various Red Cross parties sent out by the unstinted generosity of the United States give comparable information about the medical and surgical work being done by each of the belligerents In the June number Major H H Sairely tells of the work done by the unit at Kieff, behind the Galician lines from December 1914, to September, 1915 The Russian Army Medical Corps he says, takes complete charge of the wounded as far as the railroad, the Red Cross is then allowed to share in providing hospital trains in supplying nurses for war hospitals, and is indeed allowed to equip and staff base hospitals, but under military supervision, which never loses sight of any wounded man even if he be convalescing in his distant village Kieff had some 30 000 beds for wounded soldiers, but it received daily from 2000 to 12 000 cases, so all patients fit to travel were sent daily further on into Russia, by order, and at any rate 8 per cent of total cases The hospital was located in a polytechnic school and could take 750 cases in canvas cots at first, but later iron bedsteads were supplied The experiences of the hospital as regards infected wounds, lice and so on, were similar to those reported from elsewhere Cases of Asiatic cholera and typhoid fever were seen in the great military hospitals, but the civil population was unusually free from epidemics in the summer of 1915 the peasants ignorantly and ungratefully ascribing this to the absence of the doctors now away with the troops There was no vodka, of course a drunken man was an unusual event To the interdiction of vodka is ascribed the lower frequency of insanity in this than in the Russo-Japanese War Also, there was practically no venereal disease among the Russian soldiers

The Journal of Bacteriology Being the Official Organ of the Society of American Bacteriologists Bi monthly Baltimore The Williams and Wilkins Company, London The Cambridge University Press Subscription 23s per annum—It is somewhat remarkable that there is, as the publishers' announcement points out, no journal in the English language which deals with bacteriological science as a whole This gap it is the aim of this new addition to our lists of scientific publications to fill It is to be the official organ of the Society of American Bacteriologists, and is to serve also as a medium for the discussion of such general questions—of interest to all bacteriologists whether engaged in medical, technical, agricultural, or purely scientific research—as the structure and physiology of the microbes the inter relationships of microbe types the effects of physical and chemical agents on microbio life the mutual interactions of microbes growing together in various media the nutritional needs and products of metabolic activity of various microbes new advances in technique, and so on There is no doubt that such a journal is sorely needed Bacteriologists dealing with any particular section are only too apt to regard that as the only important branch of the science and it might often be greatly to their advantage to know what was going on in other fields of work As Dr W T Sedgwick says in his foreword "Bacteriology must henceforward be recognised as a broad and fundamental branch of science coordinate with rather than subervient to the other grand divisions of biology, such as medicine agriculture zoology and botany" The first number gives excellent promise The contents include a paper by Messrs Reiger Berman and Sturge on the utilisation of proteid and non proteid nitrogen which goes to show that bacteria are unable to attack and bring about the destruction of proteins without the aid of enzymes or other proteolytic agents and this appears to be true in the case of albumoses and peptones as well as for more complex proteins like egg albumen James Sherman commences an elaborate study of the protease in the soil and their relation to the bacterial flora a question of great importance in agriculture C G A Ross gives a very full account of agar which will keep the melting points high and stable for many days and even as long as 6 weeks at room temperature M M Oke states that lactose is broken up in a much more suitable culture medium for *P. coli* than lactose-peptone-extract pointing out the development of traces of many colonies from water Since the first number conclude the first number of a useful and interesting journal

A UNIQUE "EVERY CONTINGENCY" INSURANCE

The ideal insurance for professional men is one which covers (1) sickness of all kinds, (2) accidents of all kinds, (3) death, or survival to age 65. The Combined Policy of the Medical, Sickness and Accident Society has been specially drawn up to provide for all of these contingencies—the rate charged is the lowest obtainable, the Society deals *only* with medical and dental practitioners, is mutual, and was established in 1884.

EXAMPLE.

At age 30 an annual premium of £13 8s 6d will insure the following benefits—During incapacity from illness or accident, £3 3s per week for first 26 weeks and £11s 6d. per week during remainder of illness to age 65. At age 65 or previous death £300.

Sickness and accident claims are paid every week by cheque and death claims on production of satisfactory evidence. Survival claims are paid on the 65th birthday.

Practitioners should write the Secretary for full prospectus

MEDICAL SICKNESS & ACCIDENT SOC'Y.,
300, High Holborn, W C

GALE'S COMPOUND SYRUP OF THE GLYCEROPHOSPHATES with PURIFIED EXTRACT OF OX-BONE MARROW PALATABLE, STABLE, EFFICACIOUS

An elegant combination manufactured from specially selected and purified materials only. It has been found a most useful preparation for fortifying the constitution against infection, and has given gratifying results in the various forms of Anæmia, Debility, &c.

DOSE On teaspoonful.

ELIXIR ZYMETOS CO. GALE'S.

A very palatable combination of enzymes extremely useful in assisting the digestion of weakened constitutions and aiding the nutrition of patients convalescent from long and severe illnesses.

DOSE If 1 to two teaspoonfuls and after meals.

FOR THE SOUTH IS BY

THE INFANT WELFARE CAMPAIGN.

Mr B S Straus, J P, in presiding at the annual meeting of Virol, Limited, stated that it was a striking tribute not only to the power of the British Navy, but also in an especial degree to the efficiency and courage of the Mercantile Marine, that in the peculiar circumstances of the times the business of the country, with all its vast requirements, had been carried on and so large an export trade maintained.

The improvement shown by their own accounts had extended to all branches of their business, including Hospitals and Sanatoria. Public Health Authorities in connection with the Infant Welfare Movement, and the development of their home and export trade. More than 1500 Hospitals, Consumption Sanatoria, and Clinics were large and regular purchasers of Virol.

He was especially pleased to state that although manufacturing and distributing costs had risen substantially, they had as a result of a record increase in their sales, been able to show improved results without having advanced their prices to the public.

With regard to the use of their preparation by the Public Health Authorities in connection with the Infant Mortality crusade, there could be no question of the important part that proper feeding must play in the reduction of the Infant Death Rate. The universally acknowledged value of Virol, whether given to the child direct or through the agency of the mother, who herself fed her child, confirmed the belief that in this connection Virol stood in a unique position as a National Asset.

He desired also to call the attention of the Governing Authorities of our great Fever Hospitals to the consideration of the fact that the period of convalescence might be considerably shortened by more generally Virolising the diet of their patients. He felt sure that by this means very large economies could be effected in the administrative expenses of these invaluable institutions through whose wards such enormous numbers of children passed year by year.

The Report and Accounts were unanimously adopted.

JOURNALS

Quarterly Journal of Experimental Physiology Editors E A SCHÄFER W D HALLIBURTON, C S SHERRINGTON, E H STARLING, and A D WALLER Vol IX, No 4 London Charles Griffin and Co, Limited 1916 Pp 281-401 Price 7s 6d—On the Regeneration of the Cervical Sympathetic After Section, by R Tsukaguchi The experiments were made on two dogs and a number of adult cats. In the dogs, about six months after cutting out a portion of the vagus and sympathetic trunks the paralytic symptoms affecting the eye and other parts are not entirely recovered from. There is no restoration of the inhibitory action of the vagus on the heart nor of its motor effects upon the œsophagus and stomach. The histological observations indicate that the regeneration of the sympathetic has been accomplished not by its own fibres alone, but to a large extent by others of vagus origin. In cats, the regenerating fibres of the cut sympathetic first reach the superior cervical ganglion between three and four weeks after section and begin to function about six weeks after section—Notes on the Functional Regeneration of the Cut Cervical Sympathetic and Vagus By E A Schäfer and H O Feiss—Even 10 to 12 months after excision of a portion of the cervical vagus and sympathetic, there are still differences observable in the physiological conditions of the parts supplied by the sympathetic as compared with the normal side. Stimulation of the peripheral (upper) end of the cut and regenerated sympathetic evokes the usual effects after such periods, but a stronger stimulus is required than the normal side. A decidedly stronger stimulation of the lower stump is required to elicit the effects of sympathetic excitation in the eye, results which are easily elicited by stimulation of the upper stump. This appears to indicate that vagal fibres have been largely instrumental in effecting the regeneration of the peripheral sympathetic. No sign of physiological recovery of the peripheral cut vagus, one dog, five cats, could be obtained after intervals of from 10 to 13 months.—The Influence of Muscle Extract on Muscle Contraction, by S Takayasu Saline extract of muscle affects the contraction of the frog sartorius in much the same way as a saline extract which contains excess of potassium. The deleterious effects produced by muscle extract in the contraction are due to potassium. These effects can be antagonised by a small addition of calcium chloride to the extract.—The Influence of Adrenalin on the Contraction of Skeletal Muscle, by S Takayasu Solutions of adrenalin 1 in 1 000 000 show no distinct effect on the frog sartorius. Immersion in solutions 1 in 500 000 or 1 in 5000 diminishes the contractile power, the effect being most marked on the height and duration of the curve, while the latency is little affected. Muscle poisoned by immersion in solutions of adrenalin rapidly recovers on being transferred to normal Ringer. Adrenalin muscular contractions are not fatigue contractions, and are unlike those produced under the influence of veratrine, although they resemble to some extent those obtained under the influence of excess of potassium salts.—Experimental Researches on Sensory Localisations in the Cerebral Cortex by J G Dasser de Barenne Extirpation and not electrical stimulation methods have been the more prolific in advancing our knowledge of sensory cortical localisation. The author claims that his method of the local application of strychnine to the exposed uninjured cortex is a great advance on the extirpation method. Strychnine produces symptoms of excitation in the sensory sphere. Some of the author's results in his experiments on cats are as follows. Application of strychnine to a local "active zone" of the cortex causes constant and typical symptoms of excitation, but if applied outside this zone there is no like disturbance. The sensory disturbance produced affects both cutaneous and deep sensibility. The disturbances in the latter manifesting themselves in an abnormal hyperæsthesia to pinching and pressure of the bones tendons and muscles. As to the sensory functions of the skin both sides of the body are represented in the cortex of one hemisphere but on the opposite side most. The author gives a minute analysis of the localisation of the sensory areas for head and limbs. The lobus frontalis has no sensory functions in the cat. The paper is illustrated by a large number of figures of the brain and one plate.—The Effects of Thyroidectomy and Thyroid Feeding upon the Adrenalin Content of the Suprarenals by P T Herring Complete thyroidectomy has little, if any, permanent effect upon the adrenalin content of the suprarenals of the rabbit—an animal in which no characteristic

symptoms follow removal of the thyroid. In cats the adrenalin content of the suprarenals is diminished in direct proportion to the severity of the symptoms induced by removal of the thyroids.

The Military Surgeon—The last issue has a special value just now, for the reports from the various Red Cross parties sent out by the unstinted generosity of the United States give comparable information about the medical and surgical work being done by each of the belligerents. In the June number Major H H Snively tells of the work done by the unit at Kieff, behind the Galician lines from December 1914, to September, 1915. The Russian Army Medical Corps he says, takes complete charge of the wounded as far as the railroad the Red Cross is then allowed to share in providing hospital trains in supplying nurses for war hospitals, and is indeed allowed to equip and staff base hospitals, but under military supervision, which never loses sight of any wounded man even if he be convalescing in his distant village. Kieff had some 30 000 beds for wounded soldiers, but it received daily from 2000 to 12 000 cases so all patients fit to travel were sent daily further on into Russia, by order, and at any rate 8 per cent of total cases. The hospital was located in a polytechnic school and could take 750 cases, in canvas cottages at first, but later iron bedsteads were supplied. The experience of the hospital as regards infected wounds, lice and so on, were similar to those reported from elsewhere. Cases of Asiatic cholera and typhoid fever were seen in the great military hospitals, but the civil population was unusually free from epidemics in the summer of 1915 the peasants ignorantly and ungratefully ascribing this to the absence of the doctors now away with the troops. There was no vodka, of course a drunken man was an unusual event. To the interdiction of vodka is ascribed the lower frequency of insanity in this than in the Russo-Japanese War. Also, there was practically no venereal disease among the Russian soldiers.

The Journal of Bacteriology Being the Official Organ of the Society of American Bacteriologists. Bimonthly Baltimore The Williams and Wilkins Company, London. The Cambridge University Press. Subscription 23s per annum.—It is somewhat remarkable that there is as the publishers' announcement points out no journal in the English language which deals with bacteriological science as a whole. This gap it is the aim of this new addition to our lists of scientific publications to fill. It is to be the official organ of the Society of American Bacteriologists, and is to serve also as a medium for the discussion of such general questions—of interest to all bacteriologists whether engaged in medical, technical, agricultural, or purely scientific research—as the structure and physiology of the microbes, the interrelationships of microbic types, the effects of physical and chemical agents on microbic life, the mutual interactions of microbes growing together in various media, the nutritional needs and products of metabolic activity of various microbes, new advances in technique, and so on. There is no doubt that such a journal is sorely needed. Bacteriologists dealing with any particular section are only too apt to regard that as the only important branch of the science and it might often be greatly to their advantage to know what was going on in other fields of work. As Dr W T Sedgwick says in his foreword "Bacteriology must henceforward be recognized as a broad and fundamental branch of science, co-ordinate with rather than subordinate to the other grand divisions of biology, such as medicine, agriculture, zoology and botany. The first number gives excellent promise. The contents include a paper by Messrs Rettger, Berman and Sturge on the utilization of proteid and non proteid nitrogen which goes to show that bacteria are unable to attack and bring about the destruction of proteins without the aid of enzymes or other proteolytic agents, and this appears to be true in the case of albumoses and peptones as well as for the complex proteins like egg albumen. James Sherman commences an elaborate study of the proteases in a question of great importance in agriculture. C G A Jones gives a complete and valuable account which will keep the reader's eye and ear alert for many days and even as long as four weeks at a time. Temperatures M M O'Brien tells the bacteria world is a much more suitable culture medium for B. coli than lactose-peptone or bile, permitting the development of twice as many colonies from water. Some excellent abstracts conclude the first number of a useful and promising journal.

THE LANCET.

LONDON, SATURDAY, JULY 8 1916

The State Promotion of Scientific Research

At the recent Paris Economic Conference a resolution was passed urging the granting of State assistance to scientific research, while the question whether the State can usefully encourage research by granting sums of money for the purpose is naturally receiving considerable attention just now in this country, which has always been in the very front rank in producing discoverers. What we have lacked is not so much the spirit of inquiry as the faculty of applying the results of our inquiries to practical purposes. We have been too academic in this matter rather than too lazy, for as a rule, the British man of science shows irritation when asked as to the utility of this or that discovery. But it is now recognised that our immediate requirement is to swell the ranks of investigators by affording financial help, to defray the expenses of the work, to give an adequate salary to the investigator and, as a further stimulus, to offer a substantial reward for the work of research when that work has materialised into valuable practical application. The State must recognise, though few private individuals do, that negative results are often of the greatest importance and value. Failures, of course, must mean a large expenditure of material, but after all when they are the sequel to honest and intelligent work, they necessarily narrow the issues of the inquiry and advance the purpose in view. This is a truism which regularly fails to appeal to the British manufacturer who hesitates to spend more money when to his thinking, most of it is going, as he would say, 'down the sink.' He is in too great a hurry to see the fruits of research realised. It is the opposite spirit which has gained for Germany her high position in technical science. In an excellent series of articles upon the German economic position now appearing in the *Field* the expert economist who writes as 'Visitor' attributes much of German commercial success to her large class of young men equipped to pursue research in subordinate positions and at low wages and gives instances of organised search for discovery both in physics and chemistry which have been crowned with success. The Germans will spend years over an exploration when the procedures are attended by failure after failure with the conviction of gaining an ultimate triumph; it will be true that in us if we follow their lead here.

But even at such upon many provinces of science learning cannot be maintained without financial support and this can hardly be expected invariably to be paid by the State and properly and

scientifically organised, should provide the necessary funds where the proposed research is worth State interference. If results of State importance are to be realised this position is becoming inevitable in many technical branches of science. The grants from educational institutions, scientific societies, and corporations which have formed in the past the chief sources of support for research in this country, are totally inadequate for the prosecution of investigations the results of which are intended to create new industries. The Advisory Council for Research appointed by the Board of Education may do some good in bringing scientific work more intimately to the knowledge of a Government department, but more can hardly be hoped in this direction. Hitherto the sums of money granted by generous bodies and by occasional individual donors have nearly always been expended on research of an academic nature. The investigation of underlying principles is of vital importance, but the work should not stop at theoretical considerations. The possible significance of all the phenomena in industrial processes should early be studied and placed at the disposal of the manufacturer, and under conditions controlled by the State, where the State has found the money which made the research possible. The actual working details of a scheme of State aided research will need to be carefully drawn up, and precautions taken to safeguard the interests of the true and first discoverer. The Association of British Chemical Manufacturers has appointed a strong provisional committee to take steps to promote coöperation between British chemical manufacturers, who would then be in a position to place before Government information upon the chemical industry, so that industrial research may be promoted and technical organisation developed. This seems to us to be a most practical way of meeting the situation, for under such a plan there is no vague wail to the State for help, but the directions in which assistance should be given by the State are indicated by those who know.

In this connexion the scheme for the promotion of scientific research presented to the public by Mr WALTER B. PRIEST in 1905 should re claim attention particularly as he has now brought his ideas into line with present considerations. We commented favourably upon this scheme on its appearance and if its underlying principles had then gained general, and especially official, acceptance it is probable that much time would have been saved, to this country and to the whole Allied cause—time which has been spent in mere preparation—while the present inconvenience of a shortage of material in so many directions would have been obviated to a large extent. The war has opened our half closed eyes to the neglect and even discouragement displayed by the State towards scientific research. Mr PRIEST'S scheme provides for the ample compensation to the discoverer just as the Patents Act offer a pecuniary prize to the inventor. It may in fact be regarded as an extension of these Acts the clauses of which give an incentive not only to carrying out of research of industrial significance but to the prosecution of academic research

NEOCAINE-SURRENINE

NEW LOCAL ANÆSTHETIC.

Effective and SAFE.

"Neocaine-Surrenine gives marvelous results in the operation of extraction dental anæsthesia in pulpectomy, and cases of periodontitis."

Odontology Professor Choquet.

COMPOSITION.

Pure Neocaine 1 gramme
Borated Adrenalin Takamine 2 milligrammes

STABILITY — Neocaine-Surrenine is in the form of a white powder which may be kept for any length of time in closed receptacles. Partly emptied flasks should be kept dry.

APPLICATIONS.

- 1—LOCAL ANÆSTHESIA BY INFILTRATION
- 2—REGIONAL ANÆSTHESIA.
- 3—RACHIANÆSTHESIA
- 4—ANÆSTHESIA BY EXTERNAL APPLICATION

ADVANTAGES

Nature and Duration of the Anæsthesia — The anæsthesia is complete from 5 to 15 minutes after the injection, it is very deep and much more prolonged than anæsthesia with Cocaine. It lasts from 30 minutes to 1½ hours.

TOXICITY — Neocaine is 8 to 10 times less toxic than Cocaine. It does not provoke cerebral anæmia leading to syncope, it is a *cardiac tonic*.

No appreciable depressant action on the leucocytic activity, which explains the feeble toxicity of our product.

No local irritation if the injection is made aseptically.

Progressive ischæmic action without any fear of secondary hemorrhage.

TECHNIQUE.

Employ the solution 1 in 5 or 1 in 10. The concentration of the solution will be as required always taking as a basis the fact that the maximum dose of pure Neocaine-Surrenine to be employed must not exceed 1 gm. 50.

TROPICAL COUNTRIES WITH HUMID ATMOSPHERE

Our Neocaine-Surrenine "gelules" are unsuitable for exportation to countries where the climate is both very hot and humid. In this case we advise the purchase of pure Neocaine-Surrenine and ampoules, matrasces or solution already prepared in ampoules.

"Since the commencement of hostilities we employ Neocaine-Surrenine" Corbiere which has given us every satisfaction."

Pouchet and Sourdat
Regional Anæsthesia.

Sterile "Gelules" each containing 0.05 gm. or 0.50 Neocaine-Surrenine powder

Sterile "Gelules" each containing 0.05 gm. or 0.50 Neocaine-Surrenine powder

Solutions prepared in Ampoules or Flasks ready for use

Ampoules matrasces of iso-tonic sterile Neocaine-Surrenine solution, containing 50 & 100 c.c., ready for use in Regional Anæsthesia.

Full Literature and Clinical Reports on application to—

the Central Medical War Committee, has been drawn up with particular regard to urban practices. In country districts, for instance, the old question of mileage will occur and ask for separate treatment, but otherwise in country districts the arrangements for a deputy must naturally be far simpler than they ever can be in town communities, for in the country the public is limited by geography in its choice of a doctor. A method of payment in proportion to receipts, a certain maximum and minimum weekly sum being laid down, is clearly a fair proposal, but some ingenuity will be required to meet the case where the deputy seeks cash payment and the patients are always used to being given credit. But assuredly such matters can be dealt with by competent local committees.

Innotations.

Ne quid nimirum

THE SIGNIFICANCE OF THE AMINO-ACIDS

THE interesting group of bodies known as the amino acids is disclosing facts of the utmost importance in connexion with nutrition. It is well known that on hydrolysis proteins break down by resolution of the polypeptide linkings in the molecule into an assembly of amino acids, of which some 18 have been separated. Enquiry is now being developed in directions which show that each of these substances possesses its own significance—sometimes greater, sometimes less—in the processes of nutrition. Inasmuch as the proteins do not all alike resolve into the same amino acids, it is clear that their metabolic value will depend upon the kind of amino acid produced. In an interesting and lucid lecture upon the subject delivered before the Chemical Society on May 18th by Dr F. Gowland Hopkins, and now published in the June number of the society's journal, these newer standpoints in the study of nutrition—the title of the lecture—are carefully discussed. The starting point of this study is that when a mixture of all the free amino acids obtainable from protein has entirely replaced the normal intact protein of their food an adult animal maintains itself and a young animal grows. In his own experience Dr Hopkins records that scores of young animals grow sterily during experimental periods when no trace of intact protein, and no other source of flesh-forming material save amino acids, was passing their mouths. In a brief and excellent outline of the salient features of the problem Dr Frank Underhill, professor of pathological chemistry, Yale University, makes similar observations. His conclusion is that the amino acids must be regarded as food-stuffs capable of supplying the nitrogenous needs of the organism and that the chief factors to be taken into account with regard to the nutritive value of any protein or proteins are the extent and the extent of the amino acids contained therein. Since it is mainly if not entirely in the form of free amino acids and not in complex associations of these that our nitrogenous food begins to be metabolised it is obviously valuable to be able to measure the relative nutritive importance

of the different molecular groups in the protein molecule. We could then determine, as Dr Hopkins points out, whether in any particular case the withdrawal of individual amino acids deprives the animal of something essential, or whether, perhaps, the removal from the food of any particular amino acid under study may have little effect, because the animal can synthesise it for itself or dispense with it altogether. We may thus gain a further insight into the question of deficiency diseases. It should be pointed out, however, that during the use of the synthetic diets suggested as a basis of inquiry, Dr Hopkins has found that it is always essential to supply the "at present mysterious vitamin or food hormone factor." The results of the experiments are very remarkable. Thus when an animal is fed on food containing only tryptophan, histidine, tyrosine, lysine, and cystine, that is, five out of the 18 amino acids of protein, there is a remarkably slow loss of weight, and long maintenance of apparent health. On the other hand, when the five amino acids mentioned are replaced by another five of simpler aliphatic type, when leucine, valine, alanine, and glycine, together with glutamic acid form the sole nitrogen supply, loss of weight is rapid and the animal soon succumbs. A familiar case of a non-nutritional protein is gelatin, and, significantly enough, this substance on hydrolysis yields neither tyrosine nor tryptophan. The entire absence of tryptophan from its molecule stamps it at once, says Dr Hopkins, as a deficient foodstuff. Dr Hopkins goes even so far as to say that he feels it quite possible that further experiment will show that life can be maintained on a mixture from which many of the amino acids are lacking. This suggests that if nutrition can be guaranteed on a quite limited number of amino acids, the solution of the problem of artificially synthesising our food supply is brought within the region of possibility. On all fours with this are the independent conclusions of Professor Underhill in the work already referred to. Investigations of this character promise ultimately, he suggests, to lead to the assignment of more or less specific functions to the various amino acids, and hence will in direct indicate the relative efficiency of this or that protein in bringing about a desired result in nutrition. The whole story is a triumph of biochemical research.

THE TRYPANOSOMES OF SLEEPING SICKNESS

THE South African Institute for Medical Research has recently issued a pamphlet prepared by Mr G. D. Maynard, statistician and clinician to the Institute, on the Trypanosomes of Sleeping Sickness, being a study of the grounds for the alleged identity of *T. brucei* with those causing disease in man in Niasaland. The Sleeping Sickness Commission of the Royal Society in their sixteenth report seem to have satisfied themselves that the form of the malady met with in Niasaland and Rhodesia was caused by a trypanosome believed to be common to all five countries and that it was spread from wild animals to man. It was therefore recommended that efforts should be made to diminish as far as possible the number of wild animals in the areas and it was urged that every

also As Mr PRIEST points out, there are discoveries which have no marketable value and for the production of which, therefore, patent rights provide no incentives, and yet these discoveries may reveal knowledge of incalculable value. Such are the discoveries, for example, which promote the public health, and it is a question whether the incentive of a substantial reward would not attract a much larger number of workers into the field of research and lead to a bigger harvest of results. That, at all events, is what has happened in Germany, and the man who will not learn from the enemy is a pedant, not a patriot.

The Practices of Absentee Medical Officers

THE fate of the practices of members of the medical profession who have accepted, or are accepting, commissions in the Royal Army Medical Corps has not received the amount of practical attention which the importance of the subject demands. The fact that the practices of the absent medical men must in many cases suffer severely by the call which the needs of the country are making has often been insisted upon, but nothing definite has been done as yet to remedy what may become a widespread trouble and lead to frequent and infinite hardship. It must, however, be clearly stated that the neglect, which on the face of it appears to have been grave, cannot be attributed as an actual blame to anyone. It is true that no local committees have been formed with the exact intention of watching over the interests of the absentee practitioners, but the British Medical Association has made definite and strongly worded pronouncements on the necessity of those who remain safeguarding the property and professional and pecuniary look out of those who depart. It is the individual practitioners themselves who have with extraordinary light heartedness disregarded the situation. They have accepted commissions and in a large number of instances have gone from their homes without making, and without attempting to make, any provision for the abandoned patients. This is tantamount to saying that, while no machinery has been erected for protecting the interests of the temporary officers of the Royal Army Medical Corps, there has been no general demand for such machinery from the direction where it might have been anticipated. The Central Medical War Committee has now the whole matter under consideration, and the interference of this statutory body in a very difficult and important matter should be welcomed.

A scheme has been laid before the Central Medical War Committee under which local committees can be instituted, to whom there may be submitted the agreement which it is suggested should be entered into by an absentee medical practitioner with his deputy. The local committee is to be comprised of the practitioners of the district (if thought advisable the Local Medical War Committee can itself discharge the functions) and there would be relegated to it by the proposed agreement powers to deal with all disputes of

whatsoever nature arising between the absentee and the deputy in regard to any question affecting the absentee's practice, or the carrying on of the same by the deputy, the decision of the local committee being binding on both parties. Any medical man deciding to take a commission, or being called up for ordinary military service, could thus give notice to the local committee stating whether he has made arrangements with a medical practitioner or practitioners to carry on his practice in his absence, and if so giving the necessary names and addresses. To the various parties to such arrangements an agreement would then be submitted as forming a basis upon which the practice of the absentee could be carried on and restored to him upon return with, it is hoped, some approach to integrity. Under the proposed agreement the practitioner, on departing, definitely appoints his deputy or deputies, contracts for the faithful and diligent discharge of the requirements of the practice, and provides payment for the substituted service on a scale of remuneration judged by the gross receipts of the practice, and capable of readjustment every six months. The deputy undertakes to keep strict accounts and accurate entries of all moneys received, and to be responsible for the working costs incidental to the practice, which as far as possible should be carried on at the chief surgery of the practice, he also admits liability for all acts of negligence brought home to him. The scope and intentions of the scheme and the draft legal agreement are in accordance with the above summary, the Central Medical War Committee has the details under consideration.

It is quite clear that no scheme can exactly fit all kinds of practices. It may indeed be said that every medical man's practice is to some extent an individual affair requiring individual treatment if its preservation and cultivation are to be of the best. On the other hand, all medical practices have certain things in common, for with regard to them all there is a common need that when the principal is away some one should do his work for him, and prevent the practice from disappearing. Assuredly one difficulty about any scheme must be that the public cannot be ordered to accept the services of Dr A because Dr B is absent, a certain proportion of a medical man's *clientèle* will transfer themselves willingly to a nominated successor, but others will always prefer to choose a different practitioner. Each man who deputises under the suggested agreement for an absent colleague may find that he has also to look after a certain number of patients belonging to other doctors not parties to the agreement and complications may arise here requiring some exhibition of judgment and skill if they are to be met with any uniform pattern of remedy. Undoubtedly other objections more or less valid, will be forthcoming when the whole scheme is in the hands of those concerned but we cannot think that any criticisms will conceal the value of instituting a general plan for dealing with the situation the urgency of some action is admitted, and some action should be taken. The scheme which is now under the consideration of

side of the tip, at a distance of 1 cm. from the extremity, a non fluctuating lump of the size of a filbert which was lost in the neighbouring indurated tissue. On the following day the trouble increased. Articulation and even the taking of fluids were difficult and there was abundant salivation. The lump did not sensibly vary in size and the surrounding area of inflammation was almost limited to the right side of the tongue. The general condition was bad and the temperature was 104. When the formation of an abscess seemed probable the lump began to diminish and the symptoms regressed. The tongue rapidly regained its normal suppleness, but a little redness at the tip and the submaxillary adenitis persisted. On the eighth day the tumour had disappeared. The measles ran a mild course, but terminated in slight suppurative otitis. Hemiglossitis is rare. In 1879 Guéneau de Mussy reported two cases very similar to the preceding one, but in neither was any recognised infection present. The swelling was almost completely localised to the left side of the tongue, and resolution took place by the fifth day. As to the pathology of this deep glossitis, Sabrazes and Bousquet described in 1897 a case followed by a necropsy. There was an interstitial infiltration of the tongue by embryonic cells, with thrombosis of the veins. The pathogenic agent was the streptococcus. M. Sainton thinks that in his case the lump was due to inflammation of the glands of Blandin or Nuhn. The glands of this name are situated on either side of the midline at a distance from it of $\frac{1}{2}$ cm. and of 1 cm. from the edge of the tongue. The centre of the lump corresponded to this position. No doubt under the influence of the buccal inflammation of measles the gland became affected through its duct.

THE IMPORTATION OF GERMAN SYNTHETIC DRUGS INTO AMERICA

We are indebted to an American correspondent for the circular of the New York house of the Farbwerke Hoechst Company addressed to doctors in the United States informing them that—

Thanks to the good efforts of the State Department, the Allied Governments have consented to unmolested passage of a quantity of salvarsan, neosalvarsan and novocain and that the German authorities despite the abnormal conditions have now permitted the exportation of these products to the United States. The first shipment of salvarsan and neosalvarsan is on the way to this port on the *s.s. Aiguillon* which is expected to reach here the early part of the week beginning May 22nd. The only condition imposed upon us by the German Government is that strict guarantees have to be given on the part of this company that the shipments allowed to come from Germany are for use in this country only and under these circumstances there is nothing for us to do but to continue our method of distribution as practised since the outbreak of the war, without incurring a increased cost to us due to very materially increased cost of importation. We shall maintain the schedule which has been in existence since April 1st 1915 namely 100 mgm. ampule for salvarsan 0.6 gram and neosalvarsan 1.0 gram.

We are informed that while no general understanding has been given in regard to the shipment of such drugs their importation into the United States has been allowed by the Board of Trade in certain special cases. In October and November last for example certain quantities were shipped for the use of the United States Army and Navy in connection with the fact that the quantities required were at that time unobtainable elsewhere. In

December last a permit was granted for the shipment of what was stated to be a six months' supply of salvarsan and neosalvarsan for the whole of the United States of America on the understanding that at the end of the six months the United States of America would be self supporting in the matter of these drugs. In January last a similar concession was made in regard to novocain, but no other permits have been granted.

THE WELSH NATIONAL SCHOOL OF MEDICINE

It is now nearly a year since Lord Pontypridd laid the foundation stone of the new buildings of the Welsh National School of Medicine at Cardiff. Towards the erection of these buildings Sir William Thomas has given over £90,000 on condition that Treasury grants are sufficient for maintenance, while the efforts of Colonel E. M. Bruce Vaughan on behalf of the school have resulted in a contribution of over a quarter of a million of money. The war has unfortunately interfered with the carrying out of the project, and has occasioned a delay of the Treasury grant. The postponement is naturally a source of keen regret to its promoters, and must cause anxiety to all those who have the cause of medical education at heart and who view with dismay the probable shortage of medical men in the near future. We welcome, therefore, the publication in brochure form of the speeches delivered last August at the inaugural proceedings at Cardiff by Lord Aberdare, Lord Pontypridd, Sir Ivor Herbert, Sir William Thomas, Sir William Osler, and Professor E. H. Starling, and trust that they may command a wide publicity. The Royal Commission on University Education in Wales paid a visit last week to Cardiff and other university centres in Wales, and doubtless Sir William Osler's address at Bangor will substantially advance the cause of the Welsh National School of Medicine. He spoke of the purposes of a medical school as threefold: (1) the prevention of disease, (2) the solution of problems connected with the cure of disease, and (3) the teaching of medical science and practice. Judged from this broad standpoint the Cardiff scheme cannot be considered too lavish, as the provision of facilities for research in the interests of public health is as important as the training of medical students.

LUARGOL OR "102"

M. Danysz, who has for some time past made a study of the cure of trypanosomiasis, has recently added to the therapeutic armamentarium a new product under the designation of "102," consisting of a bromo argento ammoniated arseno benzol. The microbicidal properties of silver salts have been long known, whence colloid silver has come into practical use for injection and intravenous injection. The results of Danysz's experiments with this substance are given in the issue of *Il Morgagni* for June 14th and show that it is more active than other arsenical preparations in trypanosomiasis, and that small doses frequently repeated give better results than the injection of the same quantity of the remedy in a single dose. Luargol is an orange coloured powder insoluble in water but very soluble in sodic hydrate with which it forms a dark brown solution. Ten centigrammes are soluble in 1 cc. or better 15 cc. of normal sodic hydrate, and this may be used for injection diluted with sterile distilled water to 1 per cent. The apparatus supplied consists of a tube containing

wild animal destroyed or driven out would be one less source or centre of infection. The Commission at the same time admitted that there were many difficulties in the way of carrying out this recommendation. Mr Maynard, while agreeing that the conclusions of the Commission should not be treated lightly, recommends caution in entertaining them. He takes exception to the suggestion that sleeping sickness exists unrecognised in the Union of South Africa. He observes that the assumption that the disease occurs in hitherto unsuspected areas is apparently based entirely upon the presumed identity of the *Trypanosoma brucei* with the organism causing human trypanosomiasis in Nyasaland. Mr Maynard tests some of the evidence brought forward by the mathematical methods of Professor Karl Pearson, especially with regard to the morphology of the organisms. He is of opinion that the analysis of length distributions shows that the dimorphic trypanosomes dealt with—namely, *T. rhodesiense*, *T. brucei*, *T. gambiense*, trypanosomes of Nyasaland sleeping sickness, and Nyasaland wild game strain, have certain features in common. There is some evidence to suggest that there is less similarity between the Nyasaland human strain and *T. brucei* than between *T. rhodesiense*, of Stephens and Fantham, and *T. gambiense* as recorded by these authors. The analysis suggests to him that uniformity in treatment of strains, prior to the inoculation of rats, from which measurements are made, may be an important factor in determining the mean size and the variability of the components of the distributions. No valid argument in regard to the identity or otherwise of *T. brucei* and the trypanosome causing disease in man in Nyasaland, can, he thinks, be drawn at present from length measurement distributions. At the present time, Mr Maynard says, the only valid arguments in favour of the identity of the trypanosome causing disease in Nyasaland with *T. brucei* is to be drawn from experiments in regard to their pathogenicity for animals, and these, as well as such serological experiments as have been undertaken, negative, in his opinion, the supposition of identity or even of close relationship. There is, he holds, no evidence at present from the known geographical distribution of *T. brucei* to suggest that it is a cause of sleeping sickness in man, adding that even if it were found to produce disease in man this would of itself constitute no greater argument in favour of its identity with the Nyasaland human trypanosome than with *T. gambiense*. Mr Maynard expresses the opinion that from the foregoing it would appear that there is very little scientific evidence to support the contention that *T. brucei* and the trypanosome causing sleeping sickness in Nyasaland are the same species, while there are some very valid reasons for regarding them as distinct. Although the question may still be considered *sub judice* there does not seem to be any justification for entertaining a bias in favour of their identity, if this be admitted, it follows that the recommendations of the Commission, which are based on their assumed identity, do not rest on a sure foundation of fact. Mr Maynard suggests certain alternative hypotheses as possible explanations of some of the facts. Finally, he points out that unless an unmodified game strain be the cause of human trypanosomiasis—and the weight of evidence appears to him to be against this view—the human carrier is of much greater importance than the wild animal, and consequently the

recommendations of the Commission cannot, unless considerably modified, be accepted as a satisfactory solution. The wholesale destruction of the big game of Africa cannot be accomplished without profoundly affecting the economic position of the continent, nor, even if it could be satisfactorily carried out, can any positive guarantee be given that the situation in regard to sleeping sickness would be improved.

THE RELATIVE PROPORTION OF BOYS AND GIRLS BORN DURING THE WAR

THERE is a widespread belief that the proportion of male births tends to rise under the conditions produced by warfare, and that this excess of boys has in the past been a useful factor in restoring the male population of a country whose manhood had been depleted by a long campaign. It has been contended that, since famine and hardship are conditions of its production, this excess of boys does not occur in the case of the larger nations of the present world warfare, as these conditions are not present, at all events not yet. The phenomenon should be noticeable, if statistics were available, in occupied Belgium and Serbia, not in England or France. We have, however, seen a recent published statement to the effect that in France this year the number of males at birth greatly exceeds the number of females, and that in a Paris maternity hospital an overwhelming proportion of boys is being born. We do not know the authority for such statements, but the figures in our possession do not confirm them. At the Maternité Departementale in Châlons sur Marne, for which the matron in charge, Miss E. V. Pye, has furnished us the figures up to the end of May last, 122 boys and 140 girls have been born to women of the distressed area of the Marne, where, if any where in France, the conditions are those of want and of strain.

HEMIGLOSSITIS IN MEASLES

SOME catarrh of the mucous membrane of the mouth occurs in measles and may lead to ulceration, but glossitis is not mentioned as a complication in the text books. At a meeting of the Société Médicale des Hôpitaux of Paris recently M. Paul Santon reported two cases. In the first case the patient was a young soldier with such a painful swelling of the tongue that asphyxia was feared. The swollen organ projected from the mouth, and he could neither speak nor take food. The condition rapidly subsided but during the acute stage exploration of the tongue could not be carried out. In the second case the patient was also a young soldier who on the third day of a slight attack of measles suddenly complained of difficulty of mastication. Examination showed only some diffuse redness of the throat, the tongue was white, furred and red at the edge. There was submaxillary adenitis sufficient to explain the patient's trouble. But on the following day the temperature, previously normal, rose to 103.4 F., the mouth was closed and speech and deglutition were difficult. There were spontaneous pains in the tongue and all its movements were painful. It was put out with difficulty and the mouth was opened with pain. The tip was swollen and its bright red colour contrasted with the coating of fur on the middle of the tongue. Palpation which was painful showed on the right

THE USE OF AMMONIA IN THE CHLORINATION OF WATER

By JOSEPH RACE, F.I.C.,

CAPTAIN CANADIAN ARMY HYDROLOGICAL CORPS

In the course of some experiments on the effect of colour turbidity and temperature on the chlorination of water I thought it would be interesting to determine the relative efficiencies of various hypochlorites. Nothing worthy of mention was observed until ammonium hypochlorite was used. This was prepared in solution by the double decomposition of calcium hypochlorite and ammonium oxalate and great care was exercised to prevent the addition of an excess of oxalate which if present would introduce a factor of unknown value. It was anticipated that the reaction would proceed somewhat along the lines represented by the following equation—

The calcium oxalate was deposited by centrifuging at a high speed and the supernatant liquid removed for experimental work.

In testing the effect of this solution on a culture of *B. coli* communis seeded into raw Ottawa River water I was much surprised to find that the germicidal value was very much in excess of the hypochlorites of calcium sodium and potassium. The velocity of the reaction as calculated by the

$$\log \frac{N_1}{N_2}$$

formula $k = \frac{1}{t_2 - t_1}$, in which N_1 represents the number

of organisms at t_1 and N_2 at t_2 showed that with 0.3 part per million of available chlorine in each instance the value of k for ammonium hypochlorite was twenty to thirty times as great as that of calcium hypochlorite. This experiment was confirmed by others which gave similar results.

In searching for an explanation of the above phenomenon I occurred to me that it was probable that ammonium hypochlorite was exceedingly unstable in dilute solution and spontaneously decomposed into chloramine and water as represented by the following equation—

Chloramine has been shown by Rideal¹ to have a much greater germicidal action than an equivalent of chlorine. Rideal deduced this fact from experiments on the chlorination of sewage in which he found that the first rapid consumption of chlorine or hypochlorite was succeeded by a slow action which continued for some hours even days and was attended by a germicidal power after free chlorine or hypochlorite had disappeared. It became evident

that chlorine in supplement to its oxidising action which had been exhausted was acting by substitution of hydrogen in ammonia and organic compounds. The products more or less germicidal. He supported this by determining the carbonic coefficients of hypochlorite and of hypochlorite with the addition of an equivalent of ammonia. These gave values of 2.18 and 6.36 respectively. Although Rideal seems to have made this experiment merely to support his theory of explaining an observed phenomenon it is clear that the possibilities of its practical application to water and sewage disinfection seem to have been either overlooked or dismissed on account of economic considerations.

From the above mentioned facts in connection with the use of hypochlorite I followed up Rideal's work and found that the addition of an equivalent of ammonia to calcium hypochlorite at once destroyed the germicidal power as the chlorine was replaced by hydrochloric acid and ammonia chloride was also formed.

It was anticipated that the reaction would proceed somewhat along the lines represented by the following equation—

did not produce results commensurate with the increase of ammonia. Half an equivalent of ammonia, or chlorine ammonia = 4.1, gave inferior results, but the reduction in efficiency was very much smaller than the reduction in the ammonia. The relative proportions of chlorine and ammonia must also be considered from the economic standpoint and when this process is carried out on a large scale these various considerations will demand a rather fine adjustment.

A remarkable feature of the treatment of water with a mixture of hypochlorite and ammonia is the almost entire absence of absorption. On adding bleach to the Ottawa River water so as to produce a mixture containing 10 parts per million of available chlorine about 35 per cent is absorbed in five minutes at 60°F and 60 per cent within one hour. If an equivalent of ammonia is first added to the bleach, only 1.4 per cent of the available chlorine is absorbed in one hour and 3.2 per cent in 20 hours. As there is practically no absorption of the germicidal agent, the longer the contact period the better will be the results obtained. For instantaneous sterilisation the relative efficiency ratio of 3.1, for the mixture of chlorine and ammonia as compared with chlorine cannot be obtained but with increase of contact period the efficiency ratio also increases and after about 40 minutes the ratio becomes greater—3.1. The germicidal action of the mixture continues to persist on account of non-absorption and for a comparatively long time and as a consequence of this no aftergrowths are produced.

Cost.—Basing the calculations on a ratio of one equivalent of ammonia to one equivalent of available chlorine (0.5 part per million NH_3 to 1.0 part per million available chlorine)—a very conservative estimate of the most efficient ratio—this process becomes economical when the price of hypochlorite exceeds 8s. 4d. per 100 lb. This statement is based on the mixture produced being three times as efficient as hypochlorite that 33 per cent of available chlorine can be obtained from bleach and that ammonia can be purchased at 1s. per lb. The efficiency ratios of 3.1 can be obtained under the conditions of chlorination usually found, and no alteration in the point of application will be required. Bleach containing more than 33 per cent of available chlorine can be obtained but very few plants actually extract more than this amount as there are certain losses which are unavoidable. The present price of ammonia solution 16°B is quoted in the United States of America at 2½ to 2½ cents per lb. This solution contains 10.3 per cent of NH_3 and the anhydrous ammonia is therefore worth 22 to 25 cents or approximately 1s. per lb. In Ottawa bleach can be obtained for 14s. 9d. per 100 lb. and by the adoption of the ammonia process the heavy dosage of 1 part per million of available chlorine required to treat the Ottawa River water (colour 40 parts per million platinum scale) can be reduced to 0.33 part per million, with a saving of about 23s. per day or £500 per annum, if the laboratory results can be duplicated under service conditions. In the United States where much higher prices prevail for bleach the advantage to be gained by the substitution of the ammonia process is of course even greater.

Hygienic consideration.—For some years it has been considered as at least probable that the fishy odour and taste of heavily chlorinated water was caused not by the chlorine or hypochlorite but by substituted nitrogenous compounds. At first sight it would appear that by the addition of the substituted nitrogenous compounds contained in the ammonia mixture this objection would be accentuated and might deprive the process of its practical value. In practice no such result is obtained and no trace of the added mixture can be detected. As the total amount of chlorine added to the water is only about one-third of the usual dosage the total amount of chlorine compounds, nitrogenous and other, will be only one-third also and compared with taste and odour should be reduced and not increased by the adoption of the new process. As the compounds produced are of a much different character from the two cases.

Since first the foregoing I have applied the above process to a small plant treating 2,000 imperial gallons per day and have met with unexpected difficulties. When a 10 per cent solution of bleach was made and strong ammonia (28°) was added, a mass of available chlorine was formed. The mixture contained a large amount of the hypochlorite and before adding the ammonia the chlorine was almost entirely exhausted. The ammonia was added in the form of a 10 per cent solution and the mixture was allowed to stand for 24 hours before being used. The results were very satisfactory and the fishy odour and taste were completely removed.

Archives 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840,

concentrated solutions, and also that the loss could be obviated by immediate dilution with large volumes of water. The arrangements in the experimental plant are now being altered so that the ammonia and hypochlorite will only mix for a few seconds before dilution with the raw water in the intake pipe.

Although various details have yet to be worked out, these notes are published in the hope that others will take up this work and endeavour to work out a process that will give some relief from the present exorbitant price of hypochlorite.

Ottawa Civic Laboratories

PARIS

(FROM OUR OWN CORRESPONDENT)

The Influence of Syphilis on the Wounds of War

The influence of syphilis on the effects of traumatism has long been known, and is now being freely observed in military patients. The consolidation of fractures, in particular, is slower in syphilitic subjects, the callus though more profuse is more friable. Dr Sourdel a surgeon with the army, has drawn attention to several points in this connexion, mentioning that the influences of syphilis on the wounds of war manifest themselves not at first but in the later stages of treatment. A wound involving skin and muscle, for example, will be found slow in cicatrisation, the borders becoming livid and badly vascularised, but the unhealthy conditions will disappear rapidly on the application of a specific dressing like Vigo's plaster. In suppurating conditions after operations on the knee joint, after a long period of discharge there will be rapid amelioration, but there will be fistulous tracts, and these will continue to discharge with defined edges as though punched out. If a specific history is obtained, drastic treatment like the intravenous injection of cyanide of mercury will generally give good results. Syphilitic subjects are liable to secondary hæmorrhage, and minor causes—the irritation of a ligature, a drain or a small foreign body—produce in them serious results even hæmorrhages to the point of anemia. If these patients are submitted to some such specific treatment as hypodermic injection of bichloride of mercury, the tendency to hæmorrhage will disappear and cicatrisation will proceed normally. Dr Sourdel recommends the specific treatment for syphilis of every wounded syphilitic subject especially where any abnormality occurs in the course of the healing of the injury.

Public Health and the Cinema

Professor Raphael Blanchard has represented to the Academy of Medicine the advantage of using the cinema to spread valuable hygienic notions among the public in a striking manner. The idea is a sound one, and already the sanitary services have organised cinematograph displays comprising many valuable scientific records. It is altogether desirable that the spectators at these shows while being interested in the display, should learn the elementary facts concerning the diffusion of disease.

Transplantation of Cartilage in Reparative Surgery

Dr Morestin brought before the Academy of Medicine a subject of great practical interest at the present moment—viz. the role which the transplantation of cartilage may be destined to play in the vast domain of reparative surgery. Cartilaginous props have already been employed for the flaps in plastic nasal surgery. But Dr Morestin's new method consists in a wide extension of this principle in the repair of cranium and of the bones of the face. Of all the tissues none can be grafted more easily than cartilage which is not merely tolerated by the tissues into which it is transplanted, but lives and flourishes there. It has no tendency to be absorbed and only undergoes trifling modification. The graft is therefore a stable one and can be utilised with confidence. Cartilage commands itself also as a graft on account of the extreme ease with which it can be cut into any form by means of a simple bistoury. In practice it is always the costal cartilages which are employed particularly the sixth to eighth, the removal of which has no unpleasant consequences. Fragments of cartilage from another subject may also be employed. With such grafts we are in possession of an easy and certain procedure for making good losses of cranial substance even if these are large and

irregular. The method is especially suitable for replacing portions of frontal bone or of the orbital margins. Even the malar arch can be thus restored, or the greater part of the maxillary bone replaced. The hope is justified that in cases where the orbit has been extensively damaged conditions suitable for a proper prosthesis may be attained by means of cartilaginous fragments. In repairing limbs, especially the hand and foot, the procedure should have some practical application.

The Sign of the Crossed Leg in Raised Arterial Tension

A simple clinical observation may be of service in the diagnosis of increased arterial tension. The sign consists in the measurement by the eye of the shock produced by arterial momentum in the leg which is crossed over the other, a shock due to the partial obstruction produced at the level of the popliteal vessels. The patient is asked simply to cross one leg over the other in the ordinary way. Normally the upper leg does not apparently show any spontaneous movement, or it requires careful attention to note the oscillation synchronous with the arterial pulsation. But this is not the case in observing the subject of plus tension. Dr Molle has noted that oscillation due to the arterial shock begins to be apparent with a systolic pressure of 160 to 170 mm and is marked with a pressure over 170 mm. The observer should carefully watch the limb from the side, and he will be surprised at the ease with which the movement can be registered. The sign may be made still more striking by covering the limb with a piece of paper such as a folded journal when the amplitude of movement may become remarkable. The observation may be compared with one made by Delpeuch in 1900. He noted rhythmic shocks of the head when placed in certain positions synchronous with arterial pulsation in cases of aortic lesions especially aortic insufficiency.

July 4th

EPSOM COLLEGE

THE annual general meeting of the governors of Epsom College was held at the office in Soho square on June 3rd when the Treasurer, Sir Henry Morris, occupied the chair supported by many representatives of the donors.

In moving the adoption of the report, Sir Henry Morris referred to the loss which the College had sustained in the death of two of their members, Mr Thomas Boor Crosby and Mr Stanley Boyd. In reference to the reduced receipts from subscriptions as a result of the war, he mentioned that one member of the council had recently procured in less than two months a sum of over 40 guineas in annual subscriptions, and he expressed the hope that other governors would endeavour to bring the work of the foundation before their friends. He expressed the appreciation of the council at the services rendered to the College by the *British Medical Journal* and THE LANCET, adding that the British Medical Association had rendered special help in collecting contributions and that the Medical Insurance Agency had recently sent a donation of £100 which brought the total of the donations of the Agency to over £500 within a very short space of time. He expressed the regret of the council at the death of the Rev W. A. Thomas, a master of the College for 32 years who throughout that period had won the affections of many generations of boys as well as of his colleagues on the staff by all of whom he was deeply respected.

The report showed that the foundation and the trustees render assistance to 100 pensioners, medical men, the widows and aged daughters of medical men in reduced circumstances, and that 50 sons of medical men are being boarded, educated and clothed at Epsom College free of charge. The report further stated that although the numbers in the school were at first slightly affected by the war the College is now full the total number of boys being 305 as against 273 at the corresponding period last year. The report also included a good list of scholastic awards gained and mentioned that over 520 Old Epsomians are serving with the forces of whom 420 have been killed in the outbreak of war while in the roll of honours are 121 who have been killed in action and 4 who have died in hospital, 60 wounded—two of them twice and once and 11 aged. Twenty-seven Old Epsomians have been decorated by the Government and 4 of them have been mentioned in despatches.

killed) have been awarded the D S O, and 7 have received the Military Cross

After the transaction of formal business a cordial vote of thanks to the chairman for the services which he renders to the College as treasurer was carried with acclamation

The report of the scrutineers showed that the following had received the largest number of votes at the election and were consequently elected—Pensioners Isabella S V Wall (highest pensioner), Mary Molineux (ordinary pensioner), Katherine Lambkin (ordinary pensioner) Annuitants Eliza G Stevens (Morgan annuitant), Emily Wallace (Brodie Sewell annuitant) Foundation Scholars Thomas A Mason, John R Simpson, William R Pike, Alexander Shiels Robert G G Evans was also admitted a Foundation Scholar, an additional vacancy having occurred since the voting papers were issued

THE SERVICES

ROYAL NAVY MEDICAL SERVICE

In accordance with the provisions of Order in Council of April 1st, 1881, the undermentioned Fleet-Surgeons have been placed on the retired list A G Andrews E H Hodnet de Courtmacherry, and T C Meikle

ARMY MEDICAL SERVICE

Lieutenant-Colonel Sir James K Fowler K C V O, R.A.M.C. (T.E.), to be temporary Colonel

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel J S Green is retained on the Active List under the provisions of Articles 120 and 522, Royal Warrant for Pay and Promotion, and to be supernumerary Surgeon Major W S Henderson, K E Horse, relinquishes the rank of temporary Lieutenant-Colonel on reposting

Temporary Major E H Starling to be temporary Lieutenant-Colonel

Majors relinquishing the rank of temporary Lieutenant-Colonel on reposting R Storrs, J W Jennings D S O (ret), D Ahern M C Beatty, and (temporary) E L Gowlland

The undermentioned relinquish their temporary rank Major (temporary Lieutenant-Colonel) Richard B Hole and Captain (temporary Major) J W Lane

E D Hancock to be temporary Major whilst employed at the Guildford War Hospital

The undermentioned temporary Captains relinquish their commissions M L G Hallwright, O Eaton, A. Burton, W D Chambers and E P Dickinson

Temporary Captain J Craig relinquishes his commission on account of ill health

Temporary Lieutenants to be temporary Captains G H Alabaster E H Roberts, J R MacNeill, A W Harvey, H St A Agate, G M Adam, W A Alexander, F W A. Ponsford, C H Lloyd, S E Humphreys, W K Bigger, H E P Yorke, W G E Allen, R Farrar, W Reid, S Churchill, J G Willmore, W C Gowdey, F W Diamond, S C W Morris, T J Costello, J R White, W J Patterson J L Pearce, O J W Adamson, G B McCaul, S Greenwood, L L Fyfe, P B Belanger, C D Kean, F R Kirkham, P S Hopkins, T A Hindmarsh, T F Keenan A A Wilson, I E Bruneau, R T Grant, W F Law, F G O'Donohoe, F J Allen, J MacRae, A F Ross A. A O'Connor P P J Stewart E C Bowden, T C Findlater, J H Davis, W S Hall, D B I Hallett, D J Lewis, G F May, F J Rawlinson, H O Smith, J R K Thomson, W F Hare, E J Griffiths, H C Beasley, H H Kendrick, D J McLeish, H M C Green, E H Black, C R Willis, J W Coulter, D B MacLean, C F Knight, L Zealand A F Menzies, H B Lawson, H Smurthwaite, W Watkins, S R Gleed, A B Jones J M Keegan, H B Walker T E Cotta, C H Corbett, H U Leembruggen S Hodgson, J E Paterson, A St J Bateman, H F T Chambers, W W Livingston, G V T McMichael, C Banks, J D Ryan A G Christian A O'Flaherty V B Kyle J A V Mathews, R B F McKail, T A O'Brien A A W Petrie, E J Selby W R Logan A Grant T Chalmers, J W Edington A Gillespie W O Travis, C E Dolling E A Wilson C A Meaden A E Hutton J Appleyard, J Lamont, J N Donnellan, C E Droop, A C Bryson, R Nicoll J A A Orlebar E S Holloway, J T Grant O C G Shields, W H H Parsons, M C Burke G H Roberts D B Crerar G L Thornton, G H Brown W G L Wambeck J McC Lang G S Coghlan J B Boyd, N E MacDougall O E Finch, W Scott H G Hobson R Vincent A M Roome T F Craig, T Bell, T L Davies H E Rawlence H H Serpell, A Campbell, D G Wishart, R L Hutton A G Anderson D R Jones F V Hanratty R W L Wallace A C Rowwell W S Thacker J J H Ferguson J D Hart, W Fell, T C Reeves, F G W Deane, C G Galpin, R

Bruce Low, N Dunn, G M Gregoire, H P Gaston, and R Stirling

To be temporary Lieutenants D V O'Malley, K S Macky, T B A Haggard, A Morrison F E Dowling, J L Gordon, W J P Lillis, S Verdon Roe, J E Finlay, G Dougan, A F Fraser, I W Dickson, E F Hoare, G A Campbell, L Bensted, F C Morgan, A E Hunter, C W Budden, F Kinnear, J F C O'Donohoe, H E T Dawes, A W Brodribb, T H Martin, M J Loughrey, J H Fryer, P A Dykes J Graham, H Whitwell, J Lindsay, W D Hopkins, D McCormack, F H Cooke, C J B Pasley, D F Kennard, and D Campbell (from Second Lieutenant, Indian Army Reserve of Officers)

To be temporary Honorary Lieutenants whilst serving with No 8 British Red Cross (Baltic and Corn Exchange) Hospital C E Drennan, E Aylward, and S Wicks

Temporary Lieutenant R. Marshall to be temporary Honorary Lieutenant

Temporary Lieutenants relinquishing their commissions J Forbes, R McL Wishart, W W Wood, J Maxwell, T H D Storms, L E Belcourt, M R Helliwell, J J Brown, C A H Gee, W G Southey, C J Tisdall, L Valentine, A M A James, J H Rowe, J Laird, G E Beggs, J W Jackson, S R Johnston, J J Thomson, P MacKasey, G L Kennedy, W J MacNab, J Pearson, D R. Parkes, W R Taylor, P P Wright, B E Lang, O Van Luyen D E Scott, E J de Beupre, S A. Overend, C M Kellor H K Groff, R B Martin, K L MacKinnon, S K McKee, LeB B Wilmot R W McQuay, J S Chisholm, J H Fisher, E Lachopelle, W L Robertson, L J Fellow, W Turner, and B J Nolan (on account of ill health)

Temporary Honorary Lieutenant Harold L Hughes relinquishes his commission on account of ill health

Temporary Honorary Lieutenants to be temporary Lieutenants A W Adams and W L Thomas

Canadian Army Medical Corps To be temporary Captains T Coleman, W Filmer Cov J G MacNeill, W H McMillan, M G Brown, C L Blight W G Blair, A E Blackett, R A Dowd, J S Fitzsimmons, E R Graham, S E Holmes, N MacL Harris F D Sinclair, B C Reynolds, L R Shier C C Schlichter, Lieutenant A J Lomas (Canadian Militia), E Gardner, and J H Slayter

INDIAN MEDICAL SERVICE

Lieutenant-Colonel L P More, R A M.C., to be an Assistant Director of Medical Services, vice Colonel E Eckersley, A M S

Colonel W R Edwards, C B, C M G, to be Surgeon General

Lieutenant-Colonels to be Colonels J T Daly, G J H Bell, C I E, H Fooks, and W H B Robinson

TERRITORIAL FORCE

Royal Army Medical Corps

North Midland Field Ambulance Lieutenants to be Captains F C Pridham, J Howard, and D A. Wilson

East Anglian Field Ambulance Lieutenant J Humphrey to be Captain

Home Counties Field Ambulance H England and S K. McKee (late temporary Lieutenant, R.A.M.C.) to be Lieutenants

London General Hospital Lieutenant-Colonel Sir J K. Fowler, K.C.V.O., is seconded whilst holding a commission as temporary Colonel R.A.M.C. Captain F H. Humphris is restored to the establishment

Western General Hospital Captain K W Monsarrat is seconded whilst holding a commission as temporary Major, R.A.M.C.

North Midland Mounted Brigade Field Ambulance Lieutenant J M Mitchell to be Captain

West Lancashire Field Ambulance Lieutenant A. V Glendenning to be Captain

Welsh Field Ambulance Lieutenants to be Captains W Sankey and R Willan

Southern General Hospital Major R H Lucy relinquishes his commission on account of ill health

Sanitary Service R A Farrar, late temporary Major, R.A.M.C., to be Major (temporary), whose services will be available on mobilisation

London Sanitary Company Lieutenants M S Briggs and H S Tebbitt to be Captains

London Field Ambulance Captains M W K. Bird L Milton C E Petley, W J T Kimber, L B Clarke, L L Preston A F Comyn and A B P Smith, from General Hospitals to be Captains Captain H P Ashe, from a London General Hospital to be Captain

East Anglian Casualty Clearing Station Lieutenant (temporary Captain) F W Lewis to be Captain

London Casualty Clearing Station Captains W H Lloyd and W F B Bensted Smith, from General Hospitals, to be Captains

Eastern Mounted Brigade Field Ambulance Major W Archibald, to be temporary Lieutenant-Colonel whilst in command of a Field Ambulance

concentrated solutions, and also that the loss could be obviated by immediate dilution with large volumes of water. The arrangements in the experimental plant are now being altered so that the ammonia and hypochlorite will only mix for a few seconds before dilution with the raw water in the intake pipe.

Although various details have yet to be worked out, these notes are published in the hope that others will take up this work and endeavour to work out a process that will give some relief from the present exorbitant price of hypochlorite.

Ottawa Civil Laboratories

PARIS

(FROM OUR OWN CORRESPONDENT)

The Influence of Syphilis on the Wounds of War

THE influence of syphilis on the effects of traumatism has long been known, and is now being freely observed in military patients. The consolidation of fractures, in particular, is slower in syphilitic subjects, the callus though more profuse is more friable. Dr Sourdél a surgeon with the army, has drawn attention to several points in this connexion, mentioning that the influences of syphilis on the wounds of war manifest themselves not at first but in the later stages of treatment. A wound involving skin and muscle, for example, will be found slow in cicatrization, the borders becoming livid and badly vascularised, but the unhealthy conditions will disappear rapidly on the application of a specific dressing like Vigo's plaster. In suppurating conditions after operations on the knee joint, after a long period of discharge there will be rapid amelioration, but there will be fistulous tracts, and these will continue to discharge with defined edges as though punched out. If a specific history is obtained, drastic treatment like the intravenous injection of cyanide of mercury will generally give good results. Syphilitic subjects are liable to secondary hæmorrhage, and minor causes—the irritation of a ligature, a drain or a small foreign body—produce in them serious results even hæmorrhages to the point of anæmia. If these patients are submitted to some such specific treatment as hypodermic injection of biniodide of mercury, the tendency to hæmorrhage will disappear and cicatrization will proceed normally. Dr Sourdél recommends the specific treatment for syphilis of every wounded syphilitic subject especially where any abnormality occurs in the course of the healing of the injury.

Public Health and the Cinema

Professor Raphael Blanchard has represented to the Academy of Medicine the advantage of using the cinema to spread valuable hygienic notions among the public in a striking manner. The idea is a sound one, and already the sanitary services have organised cinematograph displays comprising many valuable scientific records. It is altogether desirable that the spectators at these shows while being interested in the display, should learn the elementary facts concerning the diffusion of disease.

Transplantation of Cartilage in Reparative Surgery

Dr Morestin brought before the Academy of Medicine a subject of great practical interest at the present moment—viz. the rôle which the transplantation of cartilage may be destined to play in the vast domain of reparative surgery. Cartilaginous props have already been employed for the flaps in plastic nasal surgery. But Dr Morestin's new method consists in a wide extension of this principle in the repair of cranium and of the bones of the face. Of all the tissues none can be grafted more easily than cartilage which is not merely tolerated by the tissues into which it is transplanted, but lives and flourishes there. It has no tendency to be absorbed and only undergoes trifling modification. The graft is therefore a stable one and can be utilised with confidence. Cartilage commends itself also as a graft on account of the extreme ease with which it can be cut into any form by means of a simple bistoury. In practice it is always the costal cartilages which are employed particularly the sixth to eighth the removal of which has no unpleasant consequences. Fragments of cartilage from another subject may also be employed. With such grafts we are in possession of an easy and certain procedure for making good losses of cranial substance even if these are large and

irregular. The method is specially suitable for replacing portions of frontal bone or of the orbital margins. Even the malar arch can be thus restored, or the greater part of the maxillary bone replaced. The hope is justified that in cases where the orbit has been extensively damaged conditions suitable for a proper prosthesis may be attained by means of cartilaginous fragments. In repairing limbs, especially the hand and foot, the procedure should have some useful application.

The Sign of the Crossed Leg in Raised Arterial Tension

A simple clinical observation may be of service in the diagnosis of increased arterial tension. The sign consists in the measurement by the eye of the shock produced by arterial momentum in the leg which is crossed over the other, a shock due to the partial obstruction produced at the level of the popliteal vessels. The patient is asked simply to cross one leg over the other in the ordinary way. Normally the upper leg does not apparently show any spontaneous movement, or it requires careful attention to note the oscillation synchronous with the arterial pulsation. But this is not the case in observing the subject of plus tension. Dr Molle has noted that oscillation due to the arterial shock begins to be apparent with a systolic pressure of 160 to 170 mm and is marked with a pressure over 170 mm. The observer should carefully watch the limb from the side, and he will be surprised at the ease with which the movement can be registered. The sign may be made still more striking by covering the limb with a piece of paper such as a folded journal, when the amplitude of movement may become remarkable. The observation may be compared with one made by Delpeuch in 1900. He noted rhythmic shocks of the head when placed in certain positions synchronous with arterial pulsation in cases of aortic lesion especially aortic insufficiency.

EPSOM COLLEGE

THE annual general meeting of the governors of Epsom College was held at the office in Soho-square on June 30th when the Treasurer Sir Henry Morris occupied the chair supported by many representatives of the donors.

In moving the adoption of the report, Sir Henry Morris referred to the loss which the College had sustained in the death of two of their members, Mr Thomas Boor Crosby and Mr Stanley Boyd. In referring to the reduced receipts from subscriptions as a result of the war, he mentioned that one member of the council had recently procured in less than two months a sum of over 40 guineas in annual subscriptions and he expressed the hope that other governors would endeavour to bring the work of the foundation before their friends. He expressed the appreciation of the council at the services rendered to the College by the *British Medical Journal* and THE LANCET, adding that the British Medical Association had rendered special help in collecting contributions and that the Medical Insurance Agency had recently sent a donation of £100 which brought the total of the donations of the Agency to over £500 within a very short space of time. He expressed the regret of the council at the death of the Rev W. A. Thomas a master of the College for 32 years who throughout that period had won the affection of many generations of boys as well as of his colleagues on the staff by all of whom he was deeply respected.

The report showed that the foundation and the trustees render assistance to 100 pensioners medical men or the widows and aged daughters of medical men in reduced circumstances and that 50 sons of medical men are being boarded educated and clothed at Epsom College free of charge. The report further stated that although the numbers in the school were at first slightly affected by the war the College is now full the total number of boys being 305 as against 273 at the corresponding period last year. The report also included a good list of scholars who had gained and mentioned that over 520 Old Epsomians are serving with the forces, of whom 420 have been killed in the outbreak of war while in the roll of honours are 10 and 21 who have been killed in action 4 who have died in hospital 40 wounded—two of them twice 4 who are still alive. Twenty-seven Old Epsomians have appeared at Epsom been mentioned in dispatches—4 of them were 3rd

Kensington, St. Marylebone, Hampstead, Holborn, and the City of London, and the highest rates in St. Pancras, Finsbury, Shoreditch, Bethnal Green, Poplar, and Deptford. The prevalence of scarlet fever showed a considerable decline from that recorded in the preceding month, this disease was proportionally most prevalent in the month under notice in St. Pancras, Finsbury, Shoreditch, Bermondsey, and Deptford. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals, which had been 1955, 1735, and 1606 at the end of the three preceding months, had further fallen to 1325 at the end of May, the weekly admissions averaged 155, against 210, 203, and 190 in the three preceding months. Diphtheria was rather more prevalent than it had been in the preceding month, the greatest proportional prevalence of this disease was recorded in Finsbury, Shoreditch, Stepney, and Poplar. The Metropolitan Asylums Hospitals contained 1242 diphtheria patients at the end of May, against 1533, 1417, and 1331 at the end of the three preceding months, the weekly admissions averaged 152 against 160 and 149 in the two preceding months. The prevalence of enteric fever showed but little variation from that recorded in other recent months of the 42 cases notified during May 6 belonged to the City of Westminster 5 to Kensington, 4 to Islington 4 to Wandsworth, 3 to St. Marylebone, and 3 to Stepney. There were 30 enteric fever patients under treatment in the Metropolitan Asylums Hospitals at the end of May, against 50, 46 and 39 at the end of the three preceding months, the weekly admissions, which had averaged 7 in each of the three preceding months, declined to 5 in May. Erysipelas was proportionally most prevalent in St. Pancras, Stoke Newington, Holborn, Shoreditch, Poplar, Southwark, and Bermondsey. The 36 cases of puerperal fever notified during the month included 5 in Fulham 4 in Islington and 3 each in Bethnal Green, Southwark, Lambeth, Wandsworth, and Woolwich. The 52 cases of cerebro-spinal meningitis included 6 in Islington, 5 in St. Pancras 5 in Wandsworth, 4 each in Stepney, Poplar, and Lambeth, and 3 each in Shoreditch, Bethnal Green, and Battersea. The 5 cases of

poliomyelitis belonged respectively to Islington, Hackney, Bethnal Green, Stepney, and Wandsworth.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several metropolitan boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the five weeks ending June 3rd the deaths of 5333 London residents were registered, equal to an annual rate of 12.9 per 1000, in the three preceding months the rates had been 14.5, 18.1, and 17.2 per 1000. The death rates for the month ranged from 8.5 in Stoke Newington, 9.1 in Hampstead, 9.8 in the City of Westminster and in Wandsworth 10.3 in Lewisham, and 10.7 in the City of London to 15.4 in Chelsea, 15.7 in Deptford, 16.3 in Bermondsey, 16.5 in Shoreditch and in Poplar, and 18.6 in Finsbury. The 5333 deaths from all causes included 405 which were referred to the principal infectious diseases, of these, 115 resulted from measles, 16 from scarlet fever, 34 from diphtheria, 151 from whooping-cough, 7 from enteric fever, and 82 from diarrhoea and enteritis among children under 2 years of age. No death from any of these infectious diseases was recorded in the City of London, among the metropolitan boroughs they caused the lowest death rates in the City of Westminster, Hampstead, Stoke Newington, Bermondsey, and Camberwell, and the highest death rates in Chelsea, Islington, Finsbury, Shoreditch, Poplar, Deptford, and Greenwich. The 115 deaths from measles were 82 below the corrected average number in the corresponding period of the five preceding years, this disease was proportionally most fatal in May in Islington, Finsbury, Shoreditch, Poplar, Greenwich and Deptford. The 16 cases of scarlet fever were 6 below the corrected average number, and included 2 each in St. Pancras, Shoreditch and Southwark. The 34 deaths from diphtheria showed a decline of 11 from the corrected average, and included 7 in Wandsworth, 3 each in Hammersmith, Chelsea, and Finsbury, and 2 each in St. Pancras, Stepney, Poplar, and Southwark. The 151 deaths from whooping-cough were 15 in excess of the corrected average, this disease was proportionally most fatal in Fulham,

* Including membranous croup.

Unattached List for the Territorial Force—Royal College of Surgeons in Ireland Contingent, Senior Division, Officers Training Corps Second Lieutenant A Miller to be temporary Lieutenant whilst commanding the Contingent.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 1315 1502 and 1503 at the end of the three preceding weeks declined to 1273 on Saturday last 162 new cases were admitted during the week, against 166 149, and 171 in the three preceding weeks. These hospitals also contained on Saturday last 1313 cases of diphtheria, 191 of measles 184 of whooping-cough and 47 of enteric fever, but not one of small pox. The 904 deaths from all causes in London were 107 below the number in the previous week and corresponded to an annual death rate of 10.9 per 1000. The deaths referred to diseases of the respiratory system, which had increased from 117 to 157 in the four preceding weeks, fell to 107 in the week under notice.

In the accompanying table will be found summarized complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the no. of cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the 10 diseases specified in the table was equal to an annual rate of 7.7 per 1000 of the population estimated at 4,310,000 persons. In the first 12 months the rates had been 6.0, 5.6 and 5.3 per 1000 respectively. The lower rates during the first 3 months were

THE CAUSATION AND CURE OF CERTAIN LUNACIES

To the Editor of THE LANCET

SIR.—It may not be too late to refer to a communication with the above title in your issue of June 24th. Captain Rupert Farrant, the author appears to have gone to foreign parts on service and to have left us to support with such fortitude and philosophy as we may the concussion effects of the following (amongst other) high explosives until such time as he returns as we trust he may ere long and in time to deal with the bemused claimants to his attention.

Mental cases and others have been examined for the presence of toxæmia inducing the alteration in the glands (i.e. endocrinal glands). It is deduced that many cases of lunacy may be classified according to the toxæmia present and the change that it has induced in the ductless glands.

I dare say many of us will be prepared to face yet another classification of insanity if at last we are presented with one based upon pathology. Until however Captain Farrant demonstrates a toxin or toxins in a case of insanity, and proves experimentally that such has caused a change in the ductless glands no value will be attached to this deduction.

In primary and secondary dementia atrophy of the pineal, pituitary and thyroid were found in three main groups of cases.

I do not know what is meant by "primary and secondary dementia," nor do I understand how three groups of cases are spread over two morbid states, but in any case an atrophy of these glands is not by any means found only in association with a particular variety or varieties of mental deficiency or disease. I deny that any significance whatever can be attached to this condition, upon the basis of any work done up to the close of 1914, and a considerable amount of such work had by then been recorded.

The pituitary gland was found sometimes to have given rise (sic) to symptoms of hyperpituitarism, to apitalarism in idiosyncrasy, dementia, psychosis, and other forms of insanity.

I commend this sentence to Dr. M'cormick's notice. If by it is meant that disease of a gland sometimes gives rise to specific symptoms associated with loss, impairment, or derangement of the function of that gland, that has no bearing upon the pathogenesis of any form of insanity.

Streptococci were found up to 100 per cent. and the total exclusion of bacilli in some cases of mania.

The first portion of this statement is meaningless. Is it intended to convey that the number of streptococci per gramme of faeces is increased and, if so by how much? Such was Barton White and I were able to do in this direction showed that there was no increase in these organisms in acute mania and melancholia. The second part of the statement is startling. Our experience showed that B. coli was increased in acute mania, and even Pardo (whose work I refer to in the lectures cited) who claims to have demonstrated that the putrefactive anaerobes are increased in this disorder at the expense of B. coli and B. aerogenes does not claim to have observed a complete disappearance of B. coli.

In adults certain toxæmia react on these glands especially the thyroid and pituitary and induce stimulation, hypertrophy and finally atrophy. The alteration in the amount of secretion induces an altered mental state, and this, combined with the effect of the toxæmia renders the patient insane, or liable to insanity from slight mental stress.

As to this we require evidence of the particular toxin concerned—evidence that this acts on certain glands and so acting induces the conditions mentioned, evidence that alteration in amount of secretion induces an altered mental state, evidence that toxæmia renders or helps to render a patient insane.

The whole of this utterance is *ex cathedra* valueless and unscientific, in my opinion. Of a piece with it is the further assertion that—

Alteration in the sexual glands leads to altered mentality up to insanity.

The lines on which beneficial treatment may be carried on, based on the above pathology become obvious.

Unfortunately the pathology is by no means obvious.

Toxæmia, if present, should be removed.

But all means that be done when their presence has been demonstrated.

The glands should be allowed to involute if they are hypertrophied.

Certainly by kind permission of the impresario I mean the doctor, for he dread man can of course withhold consent, prevent involution, and thus damn the proceedings.

I am Sir, yours faithfully,

Cardiff July 7th 1916

EDWIN GOODALL.

THE NEEDS OF THE ROYAL MEDICAL BENEVOLENT FUND

To the Editor of THE LANCET

SIR.—The Royal Medical Benevolent Fund, the great benevolent society of the medical profession is sorely in want of money now. Though in ordinary times the medical profession supports its own poor, in these war times this is no longer possible. At the May meeting the committee had a balance of only £17 in hand and at the June meeting was faced with a deficit of £16. The demands were heavy and had to be met, and this could only be done by withdrawing £500 from the bank. As the direct outcome of the war not only are the ordinary cases of poverty greatly increased in number, but an entirely new class of case has arisen urgently requiring relief in which, without actual poverty there is great temporary distress—distress however which it is hoped will relieve itself soon after the war is over and the doctors serving return to their civil duties.

At the outbreak of war the medical profession responded freely to the nation's call. The Territorial medical officers were at once called out, and other medical men volunteered. Both alike had to leave their practice at very short notice, and often without being able to make adequate provision for its continuance and maintenance during their absence. Their pay went but little way to supply the loss which their absence entailed for the working expenses of the practice could not be materially reduced. The result was that many families found themselves in very straitened circumstances. Rent rates, and insurance brook no delay, but, worst of all, school-bills could not be paid, and if help had not been quickly forthcoming the children would have suffered for the patriotism of their father.

The following are typical of the cases with which our Fund has had to deal—

A young doctor who had only been in practice a few years volunteered for service, and was killed in action a few days later. He left a widow aged 33, with two young boys, aged 3, and 1 year, entirely without means. The Fund voted £25 for her immediate necessities, and put her into communication with the Officers' Families Association, which gave further help.

A practitioner aged 38, earning £700 to £800 volunteered for service, leaving his practice in the hands of a neighbour who was not a success. There were two young children, and an other baby was born shortly after the husband left. The wife contracted pneumonia and nearly died. A resident patient had to leave the house. Rent and other expenses led to a debt of about £30. This the doctor could not meet, and he hurried back from the trenches to save his home from being sold up. The Fund voted £20, the Guild gave £15 the Officers' Families Association £20, and the Professional Classes War Relief Council further help with the result that he returned to the front with his immediate anxieties relieved.

A captain in the Territorials was called out and had to leave his practice in the hands of a locum who proved a failure. There were seven children, aged 2 to 14. Financial difficulties arose and payment of the school fees became impossible. Between the Fund and Guild, and Officers' Families Association, the necessary fees were raised, and clothing which was greatly required, provided.

These cases show well the way in which the Fund works, not only by giving relief itself in money and kind, but also by obtaining through co-operation with other benevolent societies more substantial assistance than it could afford alone.

But there is another class in which the distress is perhaps even greater and adequate relief more difficult. It is that of men who left home and a good practice in vigorous health and who have come back, crippled by wounds or with health impaired to a practice severely damaged by their absence and without the strength or energy to regain the practice and position which they sacrificed. Our Fund has set apart a special sum to meet emergency claims of this kind yet the demands are so great that it will soon be exhausted. We cannot now rely on the profession alone to supplement it largely for the medical profession like all other professions is hit very hard by the war and has no longer its old resources to draw upon. What is required is an emergency fund large enough to deal adequately with these emergency cases arising directly out of the war and for this we are

1 Green, in Lectures, THE LANCET, Dec 5th (p. 127), 12th (p. 13-3), 19th (p. 137), and 25th (p. 151), 1911.

St Marylebone, Shoreditch, Bethnal Green, and Stepney. The 7 fatal cases of enteric fever were 4 below the corrected average, and belonged respectively to St Marylebone, St Pancras, Islington, Hackney, Stepney, Poplar, and Lambeth. The 82 deaths from diarrhoea and enteritis among children under 2 years of age were 8 below the corrected average, the greatest proportional mortality from this cause in May was recorded in Paddington, Chelsea, Poplar, Deptford, and Greenwich. In conclusion it may be stated that the aggregate mortality in London during May from the principal infectious diseases was 21.0 per cent below the average.

Obituary.

HENRY BENJAMIN HINTON, M R O S
A CENTENARIAN DOCTOR

Surgeon Major Henry Benjamin Hinton, who has recently died at Adelaide, South Australia, was in his 104th year and the senior Member of the Royal College of Surgeons of England. He was born two years before the Battle of Waterloo at Southsea (Portsmouth) on March 7th, 1813. One of his immediate relatives was Dr James Hinton, who had secured fame as an ear surgeon—a fact which it is thought had some influence on his career, as he selected the medical profession as the field of his life's work. From 1832-34 he was a student at the London Hospital, and afterwards went to the Westminster Hospital. On May 25th, 1835, he became a Member of the Royal College of Surgeons of England. He was appointed surgeon on the East Indian *Broadholme* in 1835, and made three voyages to Calcutta. His first army appointment was as an assistant surgeon in the Bengal army in 1839. He served in the Arracan district of Burma for some three years, and then was transferred to Gwalior and assisted in tending the wounded at the battle of Maharajpore. In 1846 he was present at Aliwal in the first Sikh War and at Sobraon, and received the medal and clasp. He was at Delhi in the same year, and also participated in the second Sikh War of 1848-49 and in the Mutiny of 1857. In 1858-60 he volunteered for work in China and served with the 70th Native Infantry in Canton, and obtained the campaign medal and received a similar token for his work in the Bhootan Campaign of 1864-65. In 1869, acting on medical advice, Mr Hinton retired from the service and went to Australia. He lived in Tasmania and also in Melbourne and Geelong, and finally settled in South Australia. Mr Hinton was congratulated by the Council of the Royal College of Surgeons of England on attaining his 100th birthday in 1912 but in the same year had the misfortune to sustain a painful accident and a fractured thigh bone kept him in hospital for some time. Despite his accident he displayed extraordinary vitality until a short time before his death. He enjoyed excellent health for his years and retained his mental faculties in a wonderful degree. In his early life he was obliged to wear glasses but these he abandoned in middle age. Towards the close of his long life he could read books and write his letters without any artificial aid to his sight. He was a non-smoker, practically a total abstainer, and a small eater. Mrs L H Sholl of Adelaide, and Mr Reginald Hinton of Tasmania are the two surviving children.

DONATIONS AND BEQUESTS—The Directors of the Powell Duffryn Steam Coal Company have given £1000 towards the proposed extensions to King Edward VII Hospital at Cardiff.—The Lord Mayor of Leeds has received a contribution of £3500 from the estate of the late Mrs Sarah L S Geldart towards the extension of the Leeds General Infirmary.

QUEEN'S UNIVERSITY BELFAST—At the final degree examinations in medicine out of 35 candidates 27 passed. The success of the women candidates was remarkable. Miss Grace English was first of all the candidates gaining the £20 prize and first in obstetrics for which she was awarded the £30 scholarship. Miss M. Purce was second of all the candidates and won the £50 exhibition for being first in medicine while Mr Joseph P. McGinley was third candidate and was first in surgery and obtained the £30 prize. All three candidates were awarded first-class honours.

THE REGISTERED PRACTITIONER AND
THE UNCERTIFIED MATERNITY
NURSE

To the Editor of THE LANCET

SIR—I am directed by the President of the General Medical Council and the chairman of the Central Midwives Board to send you for publication the accompanying copy of a correspondence which has recently taken place between a registered medical practitioner in England and the chairman of the Central Midwives Board with regard to the conditions under which a medical practitioner may properly co-operate with an uncertified woman, not being a nurse employed by him, in attending a maternity case.

I am, Sir, yours faithfully,

G W DUNCAN,
Secretary Central Milk Producers Board

Westminster S W July 3rd 1916

{ COPY }

DEAR SIR,—Do you mind telling me if, in your opinion the following case is that of 'covering an uncertified midwife'? Mrs —, who was in practice before the Act and who has since been crossed off the Roll, or to be strictly accurate, has resigned, still acts as a nurse, and tells everybody who comes to her that she cannot act without a doctor, and sends all the people to me. Am I justified in going to them? The instruction I give is that they are to send for me directly they want me, and in the event of the child being born before I arrive that the placenta is always to be kept for me to see

As I have been in practice over 35 years, and done a good deal of midwifery, I am naturally anxious not to break the law, and sooner than do that would rather tell Mrs. — that I cannot go with her, either as a nurse or in any other capacity. I am sorry to trouble you, but believe you are the chairman of the Central Midwives Board.

Yours truly,

June 8th 1916

DEAR SIR,—In reply to your letter of June 8th, forwarded to me, in such a case as that which you mention—the woman having already been struck off the Midwives Roll or having resigned—

You must take care that it is clearly understood that our patients whom you attend with Mrs. — are your patients and not hers, though she may have sent them.

In any dispute on this point the C M B always goes on this principle, that the case belongs to the person who has undertaken to attend the confinement whenever it occurs (day or night) even if normal. A monthly nurse summons the doctor so that he may conduct the delivery.

In many of the disputed cases it has been plain to the Board that this arrangement has not been made but that the midwife and doctor have agreed that the doctor should not be called at night except in case of some abnormality or that he should not be called to deliver at any time except in case of some abnormality.

In these cases the Board holds that the case belongs to the woman, and that the doctor is covering her

In your case I should write your instructions to the mil
wife and should keep a copy in case of any dispute

There is nothing to prevent Mrs — from acting as a monthly nurse under your orders. You are responsible for the cases and for Mrs — nursing of them.

I am glad to help you and only wish that more practitioners would adopt the course which you have adopted.

Believe me, yours very faithfully
F. H. CHAMBERS

Littlehead Valley Lehigh June 12th 1861

DEAR SIR — I am more than grateful to you for your letter
and advice. I have written to Mrs. — and enclose a son's
copy.

I wish to carry out the Act both in the spirit as well as the letter and am naturally anxious not to run any risk myself.

With kind regards

June 11th 1915

0155

To Mrs. ——— I have not completely finished
with you I have a number of letters to write
in relation to my daughter's education. I
exception to this. I have not time to say
other than to say that I am very much
sincerely yours I am
June 1st

THE CAUSATION AND CURE OF CERTAIN LUNACIES

To the Editor of THE LANCET

SIR,—It may not be too late to refer to a communication with the above title in your issue of June 24th. Captain Rupert Farrant, the author, appears to have gone to foreign parts on service and to have left us to support with such fortitude and philosophy as we may, the concussion effects of the following (amongst other) high explosives until such time as he returns, as we trust he may ere long, and in fettle to deal with the bemused claimants to his attention.

Mental cases and others have been examined for the presence of toxæmia inducing the alteration in the glands (i.e. endocrinal glands). It is deduced that many cases of lunacy may be classified according to the toxæmia present and the change that it has induced in the ductless glands.

I dare say many of us will be prepared to face yet another classification of insanity if at last we are presented with one based upon pathology. Until, however, Captain Farrant demonstrates a toxin, or toxins, in a case of insanity, and proves experimentally that such has caused a change in the ductless glands, no value will be attached to this deduction.

In primary and secondary amentia atrophy of the pineal pituitary and thyroid were found in three main groups of cases.

I do not know what is meant by 'primary and secondary amentia' nor do I understand how three groups of cases are spread over two morbid states, but in any case, an atrophy of these glands is not by any means found only in association with a particular variety or varieties of mental deficiency or disease. I deny that any significance whatever can be attached to this condition, upon the basis of any work done up to the close of 1914, and a considerable amount of such work had by then been recorded.

The pituitary gland was found sometimes to have given rise (sic) to symptoms of hyperpituitarism, to apituitarism in idiocy, dementia præcox, and other forms of insanity.

I commend this sentence to Dr Mercier's notice. If by it is meant that disease of a gland sometimes gives rise to specific symptoms associated with loss, impairment or derangement of the function of that gland, that has no bearing upon the pathogenesis of any form of insanity.

Streptococci were found up to 100 per cent, and the total exclusion of bacillus coli in some cases of mania.

The first portion of this statement is meaningless. Is it intended to convey that the number of streptococci per gramme of faeces is increased and, if so, by how much? Such work as Barton White and I were able to do in this direction¹ showed that there was no increase in these organisms in acute mania and melancholia. The second part of the statement is startling. Our experience showed that B coli was increased in acute mania, and even Pardo (whose work I refer to in the lectures cited) who claims to have demonstrated that the putrefactive anaerobes are increased in this disorder at the expense of B coli and B aerogenes, does not claim to have observed a complete disappearance of B coli.

In adults certain toxæmias react on these glands especially the thyroid and pituitary and induce stimulation hypertrophy and finally atrophy. The alteration in the amount of secretion induces an altered mental state and this combined with the effect of the toxæmia, renders the patient insane, or liable to insanity from slight mental stress.

Am I justified in going to them? The instruction I give is that they are to send for me directly they want me, and in the event of the child being born before I arrive that the placenta is always to be kept for me to see

As I have been in practice over 35 years, and done a good deal of midwifery, I am naturally anxious not to break the law, and sooner than do that would rather tell Mrs. — that I cannot go with her, either as a nurse or in any other capacity. I am sorry to trouble you, but believe you are the chairman of the Central Midwives Board.

Yours truly,

June 8th 1916

DEAR SIR,—In reply to your letter of June 8th forwarded to me, in such a case as that which you mention—the woman having already been struck off the Midwives Roll or having resigned—

You must take care that it is clearly understood that any patients whom you attend with Mrs. — are *your* patients and not hers, though she may have sent them.

In our dispute on this point the C.M.B. always goes on this principle, that the case belongs to the person who has undertaken to attend the confinement whenever it occurs (day or night) even if normal. A monthly nurse summons the doctor so that he may conduct the delivery.

In many of the disputed cases it has been plain to the Board that this arrangement has not been made, but that the midwife and doctor have agreed that the doctor should not be called at night except in case of some abnormality, or that he should not be called to deliver at any time except in case of some abnormality.

In these cases the Board holds that the case belongs to the woman, and that the doctor is covering her

In your case I should write your instructions to the wife and should keep a copy in case of any dispute.

There is nothing to prevent Mrs. — from acting as a monthly nurse under your orders. We are responsible for the cases and for Mrs. — nursing of them.

I am glad to help you and only wish that more practitioners would adopt the course which you have adopted.

Believe me yours very faithfully

Littlehead Valley Lake 1 June 12th 1 5

DEAR SIR - I am more than grateful to you for your letter and advice. I have written to Mrs. — and enclosed you a copy of my letter to her. I hope to be in the spirit as well as

I wish to carry out the Ac. both in the spirit as well as the letter and am naturally anxious to do so and risk myself.

Myself	100%
With kind regard	100%

[illegible]

The War.

THE CASUALTY LIST

THE following names of medical officers appear among the casualties announced since our last issue —

Killed

Captain K H A Kellie R.A.M.C., was educated at Cambridge and at St George's Hospital, London, and qualified in 1905. He was a well known rowing man, and held appointments at several London hospitals, and was in consulting practice in Queen Anne street before joining the R.A.M.C. in April, 1915.

Lieutenant J B Haverson, R.A.M.C., who came over with the Canadian Contingent, graduated at the Manitoba Medical College in 1915.

Died

Major G H M Dunlop, R.A.M.C., qualified M.B. at Edinburgh University in 1889 and was in practice at Abercrombie-place Edinburgh, when war broke out.

Lieutenant J St J Dundon R.A.M.C., qualified recently and thereupon joined the R.A.M.C.

Captain N J Hofmeier South African Medical Corps

Wounded

Captain T C Clarke R.A.M.C.

Lieutenant E C Lambert, R.A.M.C. attached to the East Surrey Regiment

Lieutenant R C B Briscoe R.A.M.C.

Lieutenant D St C Creighton, R.A.M.C. attached to the Royal Field Artillery

Lieutenant V F Stock, R.A.M.C.

Lieutenant J Unsworth, R.A.M.C.

Captain N Black R.A.M.C. attached to the Argyll and Sutherland Highlanders

Captain W T Smith, R.A.M.C., attached to the King's Liverpool Regiment

Believed to have been taken Prisoner at K el-Amara

Major E F E Baines, L.M.S.

DEATHS AMONG THE SONS OF MEDICAL MEN

The following sons of medical men must be added to our list of those who have fallen during the war —

Armourer Corporal I O'D Watson, 10th Battalion Canadian Infantry only son of the late Lieutenant-Colonel J Watson, R.A.M.C.

Lieutenant E H Bird, Royal Fusiliers, attached to the Royal Flying Corps second son of the late Dr A. H. Bird.

Lieutenant H. A. Llewellyn South Wales Borderers, only son of the late Dr J D Llewellyn of Bargoed South Wales.

Lieutenant J J Ball, Royal Field Artillery, only son of Dr J B Ball of Upper Wimpole-street London.

Private C P S Morris Canadian Infantry son of Dr C E Morris of London Ontario.

MENTIONED IN DESPATCHES

In a despatch received from Lieutenant-General J C Smuts Commander in Chief of the East African Force, dated June 30th, 1916 the names of the following medical officers are mentioned —

— Maj R T Brown R.A.M.C. Col. (temp Surg Gen.) G D Benfer C.B. C.M.G. D.S.O. A.M.S. Lt.-Col. C A Johnston L.M.S. Lt.-Col. C J O'Gorman D.S.O. R.A.M.C. Lt.-Col. R G Turner L.M.S. Feridic Imperial Service Sappers and Miners—1st Class Sub.

Asst. Surg. Major Abdul E. L.A.M.C. Medical Corps—Capt C V Thorn on

— Asst. Army Medical Corps—Capt S G Grinstead.

— Asst. Army Medical Corps—Lt.-Col. A D Milne Cap J McP

— Asst. Medical Corps—Maj E T Harris Maj C G Seymour

— Asst. Subordinate Medical Department—3rd Class Assist Surg A R Emmett

In a despatch received from General Sir Beauchamp Duff Commander in Chief in India, the names of the following medical officers are mentioned —

— Col F R Coppinger R.A.M.C. Maj T B Kelly L.M.S. Lt.-Col L F Smith R.A.M.C. Lt. J S Towler R.A.M.C. (L.F.) Asst.

— Asst. E H Gillen L.M.S. Maj G E Cathcart R.A.M.C. Lt.-Col B E Chatterton L.M.S. Cap J Cunningham L.M.S. Maj J E S Fleming L.M.S. Lt.-Col R J W Mawhinney R.A.M.C. Maj G F

— Asst. Surg A. Quick

The names of two civilian medical men, Dr A. Macrae and Dr J C Young of the K el-Amara Mission, are also mentioned.

OBITUARY OF THE WAR

SIDNEY EDWARD PUNCH, L.R.C.P. & S. IREL.,

SURGEON ROYAL NAVY

Surgeon S E Punch, who lost his life on H.M.S. *Indefatigable* in the naval engagement of May 31st was in his thirty first year and son of the late Philip Edward Punch of Ardfoyle, Cork. He was educated at Clongowes Wood College, Co Kildare, and Ampleforth College, Yorkshire, and then spent five years in his father's office (wholesale tea merchants) before entering University College Cork, as a medical student. After studying in Dublin he passed his qualifying examination in 1912, entering the navy three months later. Surgeon Punch was good at field sports, he played in his University College Rugby fifteen and in the cricket eleven, was fond of sailing, and had won prizes in diving competitions.

A senior colleague writes thus of Surgeon Punch: "Though only four years in the Naval Medical Service before meeting his death Sidney Punch had already endeared himself to hundreds of naval officers and men. His was a charming personality, always cheery—sometimes under circumstances that might well depress many another man—willing to help others, a loyal and cheerful assistant. He took part in all sports, and was ready to take as good as he gave. Punch was, to sum up in a single sentence, 'A good Irishman'."

HUGH LEIGH NORRIS M.R.C.S. ENG., L.R.C.P. LOND.,

FLEET SURGEON ROYAL NAVY

Fleet-Surgeon H. Norris, who was lost on H.M.S. *Indefatigable* in the naval engagement on May 31st was son of the late Dr Henry Edmunds Norris of Charmonth, and grandson of Captain Maryat, the famous writer. He was educated at Dulwich College and St Thomas's Hospital qualifying in 1893 and entering the navy in the same year.

Fleet-Surgeon Norris's activities were not confined to his professional work; he was an artist of some ability and his sketches were of use to the service. Following in his grandfather's footsteps he published two books "Rice Papers and China Side" besides contributions to various journals, including *Punch*. He was good at games a good average football player, and devoted to sailing.

A colleague writes of Fleet-Surgeon Norris: "It was on his return home from abroad where he had seen active service, and at the Royal Naval Barracks Portsmouth to which he had been appointed, that I renewed my friendship with Norris and again enjoyed his genial wit and ready smile and the many qualities which so endeared him to his messmates. By his medical colleagues and patients alike he was deservedly held in high esteem, for he possessed a high professional knowledge and an intimate comprehension of the

driven to appeal to the public as well as to our own profession

We trust that our appeal will meet with a liberal response both from the public and from the medical profession for unless fresh funds are quickly forthcoming it will be impossible to continue the relief which is so urgently required—We are, Sir, yours faithfully

JOHN TWEEDY, President
SAMUEL WEST, Hon Treasurer
G NEWTON PITT, Hon Secretary

11, Chandos street, Cavendish square,
London W July 1st 1916

THE MEDICAL DIRECTORY

To the Editor of THE LANCET

SIR,—Our annual circular has been posted to the profession to-day. In view of the difficulties in obtaining labour, we are most anxious to have returns made to us as promptly as possible. We hope that practitioners who are serving in the navy and army will have arranged for their circulars to be forwarded to them.

We are, Sir, yours faithfully,

July 4th 1916

J AND A CHURCHILL

WOMEN STUDENTS AT THE LONDON HOSPITALS

To the Editor of THE LANCET

SIR,—I note that in your issue of July 1st Professor W D Halliburton states "that St George's Hospital has made a step forward in admitting a limited number of women students to 'their' wards, and that the experiment has proved such a complete success that he is hopeful that other hospitals will follow their example." Professor Halliburton, however, does not mention the fact, of which he is doubtless aware that St Mary's Hospital has already thrown open its doors to women students at the request of the authorities of the London School of Medicine for Women.

Since May 1st women students have been admitted to the wards of St Mary's Hospital for clinical instruction, and at the present time 12 are working there. This number, it is expected, will be largely augmented in October. No request was made for admission of women students to courses of instruction in preliminary or intermediate subjects.

In justice to St. Mary's Hospital Medical School I have thought it my duty to place these facts before you.

I am, Sir, yours faithfully

July 3rd 1916

JOHN F H BROADBENT,
Dean of St. Mary's Hospital Medical School

SPINAL ANÆSTHESIA, WITH REFERENCE TO ITS USE IN THE TRENDLENBURG POSITION

To the Editor of THE LANCET

SIR,—Will you allow me to add the following remarks to my paper on the above subject in answer to Mr A G Stewart's letter, which appeared in your issue of June 24th?

In the case of the child aged 3 the injection was made in the third lumbar space, in the others in the second lumbar space. I was aware of the continental work done in relation to this position and I heard Professor Jonnesco give his interesting lecture on high spinal anaesthesia at the Royal Society of Medicine in 1909 and of course, did not mean to claim any originality. As to the general anaesthetic given in combination, I have used spinal anaesthesia in the dorsal position in many abdominal operations without any general anaesthetic but our object in these cases in giving a very small amount of general anaesthetic was to prevent psychic shock and to go away with the discomfort of the position. I am Sir yours faithfully

July 3rd 1916

H M PAGE

ALIMENTARY REST IN DIABETES

To the Editor of THE LANCET

SIR—Your leading article in to-day's issue does very scant justice to F M Allen. Allen bases his methods of treatment upon experimental work on animals and not upon hypotheses, in this it differs from that of Guelph. Many of

his followers have taken but a few steps along his path and failed to see the goal. The word "drastic" when applied to a treatment is misleading. The prolonged fast is an essential part of the treatment and any case which is submitted to alimentary rest until sugar disappears from the urine has not been treated by Allen's method and should not be included in records under that heading. The reason the fast is not that it leads to the disappearance of sugar from the urine—that observation is simply a consequence of the method of determining that the fast has been of sufficient duration—but that it leads to an alteration in metabolism which permits a greater katabolism of carbohydrates. In my experience the severe cases prove the value of the method, the chronic cases yield to treatment which does not test so severely the control of the patient.

Although many hundreds of cases have been treated in America, many suffering from severe disease, with happy results, let us wait until we have more evidence before we pass judgment but do not let us prejudice the case by asserting that the treatment is of less value in severe cases than in mild.—I am, Sir yours faithfully,

Portland place W July 1st 1916.

O LEVYON

THE STRETCHING OF SCAR TISSUES IN MOUTH LESIONS

To the Editor of THE LANCET

SIR,—The description of a simple device for stretching scar tissue associated with mouth lesions may perhaps be of some value at the present moment. Its use applies particularly to those cases where the lip and cheek are bound down by scar tissue to the subjacent structures. The apparatus consists of a ring made with rubber tubing into which wire is introduced the free ends of the tubing being fastened together to form a complete ring. The ring is placed between the lip and cheek on the one side and the gum supported by bone on the other side in such a manner as to bring pressure to bear upon the scar tissue. By increasing the size of the tubing and the tension of the wire the pressure can be increased without causing discomfort to the patient beyond the presence of the apparatus. No special tubing has been used most frequently at the commencement. The wire used is similar to that used as a driving cord for dental engines, it is twisted spirally. The ends of the tubing are fastened together with rubber solution one end being made to overlap the other.

Previous to the introduction of this apparatus I had for some years been using pads of cotton wool and strips of tubing which has not been strengthened, but used chiefly in a U form. The chief use formerly has been to free the lip in cases of hare lip. The method was referred to before at the recent discussion upon injuries of the jaws at the Royal Society of Medicine.

I am, Sir, yours faithfully

W WARWICK JAMES

Park-crescent, Portland place W June 27th 1916

ENTERIC FEVERS IN THE TROPICS A POINT IN NOMENCLATURE

To the Editor of THE LANCET

SIR—With reference to the slight change which has been made in the heading of the section referring to typhoid and paratyphoid fevers in the August number of the *Tropical Diseases Bulletin* it may be safely said that the medical profession is no satisfied with the present classification of the 'typhoid fevers' or with that of the bacilli which cause the separate infections. There is a fairly well marked group of enteric fever having certain features in common and if those diseases are grouped under the word 'typhoid' the bacilli naturally fall into a group corresponding with *Enterica typhosa* = *B typhosa* = *B paratyphosa* and *B paratyphosa* = *B paratyphosa* = *B paratyphosa*. To call a case of such character of non-relapse fever a 'typhoid' or a 'major' would only create further confusion. The suggestion is made with a view to a true and satisfactory state of affairs.

I am Sir yours faithfully

J H TILLMAN

King's College Hospital, London W June 27th 1916

artificial abscesses and for the detection of egg albumin in urine, as well as a note on the jaundice caused by the ingestion of picric acid

Tests for Turpentine and Paraffin in the Pus of Artificial Abscesses

Microchemical tests.—The pus from an abscess caused by turpentine or paraffin contains oily globules visible on microscopical examination. Just as fats do, these globules reduce osmic acid in presence of Nile blue. Paraffin, a golden yellow turpentine brownish yellow. The action of the staining agent attains its maximum if we take the precaution to deposit it behind on the glass slide on which the pus is to be spread by simple evaporation of a drop of the alcoholic solution. Nile blue 0.25 gm in 20 c.c. of 50 per cent alcohol. In contrast with the vegetable oils fatty globules of vaseline or oil of vaseline possibly derived from the dressings, the droplets of turpentine or paraffin derived from the pus are larger and moreover are alone soluble in ethylaldehyde. To a certain extent such is the case we introduce one or two drops of aldehyde between the slide and the cover-glass stained with Nile blue watching under the microscope the action of the solvent on the tinted droplets.

Microchemical tests.—If we treat pus from such an abscess with alcohol at 50° (2 c.c. of pus in 5 c.c. of alcohol) and turpentine or paraffin therein contained will be dissolved. (a) If to 2 c.c. of water we add two drops of the preceding alcoholic solution and one drop of oil of nutmeg commercial formal we witness a deep-brown granular tint if the pus contains paraffin. (b) The alcoholic solution (5 to 10 c.c.) poured into a large quantity of water (500 c.c.) saturated with picric acid when shaken leaves on the surface of the liquid droplets or an oily ring coloured orange-yellow in the case of paraffin colourless in presence of turpentine. The smell will enable us to distinguish between turpentine and paraffin. (c) A small quantity of butter of antimony (SbO₂) on a platinum wire plunged into the air of the recipient turns reddish-brown in presence of turpentine vapour (Pilsbury's test). (d) Lastly in a subject who has induced abscess formation by the injection of essence of turpentine the urine often presents an odour of violets when passed.

The Detection of Egg Albumin in Urine

Egg-albumin is often made use of in order to simulate albuminuria. A little white of egg is beaten up with plain water and allowed to deposit. Only the upper part of the liquid, containing very little albumin is employed. In some instances the malingeringer himself injects it into the urethra or into the bladder by the aid of an ordinary gonorrhoeal syringe. In others he keeps it in a small phial which he hides up his sleeve, and adds it to the urine as he passes it. To determine the presence of egg-albumin proceed as follows. (1) Take 5 c.c. of the suspected urine and introduce right to the bottom of the tube without mixing 5 c.c. of Maurel's test solution. Should the urine contain egg albumin a precipitate forms either at once or in the course of a few minutes at the line of junction of the two fluids. On mixing the two fluids the precipitate rapidly increases. This gives no precipitate with sera-albumin. In some rare instances however in the absence of egg albumin we meet with a precipitation ring when the urine contains a large proportion of aceto-soluble ordinary albumoses, or blood, but on shaking up the precipitate dissolves or at any rate does not increase. A mixture of equal parts of ordinary commercial formal and glacial acetic acid behaves like Maurel's test solution. Maurel's test solution has the following composition. Solution of cupric sulphate 33 per cent. 25 c.c. solution of sulphate of copper 5 per cent. 5 c.c. glacial acetic acid 70 c.c.

Biological reactions.—When we obtain a positive reaction with Maurel's solution and the aceto-formol solution the biochemical reactions of the precipitates must be ascertained in a suitably equipped laboratory. With this object in view prepare rabbit anti-ovalbumin by the repeated subcutaneous injection at six days interval (six in all) of 2 c.c. of pure ovalbumin obtained under aseptic conditions. The rabbit blood is obtained by introducing a platinum needle into the marginal vein of the ear. The blood is allowed to coagulate the supernatant serum is decanted and placed in 5 c.c. ampoules then being placed for half an hour in the warm chamber at 37° C. The test is applied as follows: Pour 1 c.c. of the filtered urine into a small test tube (same as used for Wassermann reaction). Introduce 8 drops of anti-ovalbumin. The drops of serum fall to the bottom of the tube and set up a copious precipitate if the urine contains ovalbumin. In the contrary event the urine remains clear. The serum must not deposit in presence of normal solution or normal urine. These tests do not exclude other methods of investigation nor the close observation of the subject, washing out the bladder &c. Sometimes the malingeringer operates more clumsily making use of a strong solution of ovalbumin in which case the proportion of albumin is necessarily high with numerous threads and colourless globoid masses easily seen by oblique illumination floating in the urine.

A Jaundice Caused by the Ingestion of Picric Acid

Picric acid in the organism is transformed by reduction into picramic acid and even in a more advanced derivative, triaminophenol and others which are eliminated in the urine. It is very uncommon to find traces of actual picric acid. In order to form an idea as to the nature of the products eliminated and the duration of the elimination of a small quantity of picric acid just enough to provoke slight jaundice an assistant was good enough to swallow 20 centigrammes of the powder in a cake. Within two hours and a half his urine began to show traces of reduction products more advanced than picramic acid. The proportion steadily increased and seven hours after the ingestion of the acid traces of picramic acid began to appear. On the morning of the 2nd hours after ingestion—the selerotics were faintly jaundiced and at the same time the urine became pomegranate red. This slight jaundice which might easily have escaped notice only lasted seven or eight hours. The next day the colour of the urine had returned to its normal yellow though a shade darker than usual. In the mean time a large quantity of picric acid may take upwards of 20 days. Picramic acid is turned yellow by strong acids red by alkalies. The picramates are very soluble in water whereas picramic acid very slightly so. It is readily taken up by organic solvents especially acetic ether, ordinary ether and chloroform. Picramic acid is a fat stain

for wool colouring it a reddish brown. The colour of picramic urine is usually orange-red (pomegranate) varying in depth sometimes blood red or almost black. Nevertheless a urine normal in colour may contain traces of picramic acid without being red in which case there is usually no concomitant jaundice. With acids the red colour turns yellow. For instance in testing for albumin with ascorbic sulphosalicylic acid or nitric acid, we get a yellow zone above the acid. Picramic urine normally acid remains sweet for a long time. In neutral or alkaline urine on the contrary the picramic derivatives disappear more or less rapidly within a few hours from the urine. It is therefore important to make the examination as soon as possible after the emission of the specimen.

M. de Lillothoud has provided us with a very delicate test for traces of picric acid as also of picramic acid and the more advanced reduction products. Pour 2 c.c. of the suspected urine into a test tube and 1.5 c.c. of ammonia. Shake and introduce with a drawn-out pipette about 1 c.c. of the ferrous tartrate test solution (free ferrous sulphate 2 grammes, tartaric acid 10 grammes, water 100 c.c.) conveying it to the bottom of the test tube. At the junction of the two layers we get a ring of more or less deep cherry red colour best seen against a white background with the back to the light. When the urine contains more advanced reduction products than picramic acid we see below the red ring from which it is usually separated by a colourless area, a blue ring of variable intensity. The diazo-reaction invented by Mr. Derrien for picramic acid is less sensitive. Into a test tube containing 2 c.c. of the suspected urine put one drop of sulphuric acid (25 per cent) and two drops of a 1 in 1000 solution of nitrite of soda. Heat exactly one minute in a boiling water bath, cool under a stream of cold water. Add 5 c.c. of ether and three drops of ammonia saturated with naphthol. On shaking up, the ether assumes a violet red colour. If we add to picramic urine a solution of subacetate of lead drop by drop shaking well after each addition, at a given moment he precipitate assumes a flesh or salmon tint. The addition of chloride of barium causes an orange precipitate varying in depth.

To extract picramic acid from urine in order to afford convincing evidence of its presence and at the same time to provide a *pièce de conviction* we proceed as follows. Into a decantation vessel pour about 100 c.c. of urine slightly acidified with a few drops of acetic or phosphoric acid (for very dark urines 10 c.c. will be sufficient, while for yellow urines we must use as much as 150 or 200 c.c.) add about 25 c.c. of acetic ether then having corked the bottle shake up thoroughly in order to dissolve the picramic acid. Set aside separate the lower liquid (if the acetic acid should have formed an emulsion this is broken up by adding a few drops of alcohol or by filtering the liquid through a plug of cotton wool). Exhaust the urine twice more with acetic ether (15 c.c. each time). The acetic ether coloured a more or less orange-yellow is filtered then slowly evaporated in a little capsule with a few inches of woollen thread. To the residue add 500 c.c. of water heat for 10 or 15 minutes in a boiling water-bath or nearly to boiling point. Place the skin of wool in a little glass vessel squeeze it with a glass rod against the edge of the recipient and wash with a few drops of water. Then wash in plenty of water soap well, rinse and dry. Apply the ferrous tartrate and the diazo-reaction test to the liquid left in the capsule mixed if necessary with that in the glass. Part of the dried wool will serve as *pièce de conviction* and is annexed to the report. Later on should any doubt remain in the mind of the jury some other expert can discover the presence of picramic acid for himself. The rest of the wool is placed in a test tube with 2 or 3 c.c. of water and three or four drops of ammonia. On heating the picramic acid dissolves giving an orange-yellow colour of variable depth to the liquid in which the presence of picramic derivatives can be revealed by the ferrous tartrate test and the diazo-reaction. Acetic ether can be replaced by ordinary ether or chloroform. In some instances especially when the urine is not clear it is better to clarify it by means of a 10 per cent solution of Courtonne's liquid (neutral acetate of lead) before commencing the test. Or we may add to the urine 10 or 100 c.c. according to the tinge a slight excess of chloride of barium. The precipitate washed in a small quantity of water is decomposed by means of a solution of sulphate of soda and a few drops of sulphuric acid. Exhaust with acetic acid or ether and continue as above.

Although these may not be the favourite forms of malingering, if it exists in this country, the notes are nevertheless suggestive of the kind of evidence which it is desirable to adduce in these very difficult cases. The number of cases of malingering in either the French or the English army has been extraordinarily few.

PHYSICAL CLINIQUE FOR WOUNDED AND DISABLED SOLDIERS.—This institution has now been opened at 126 Great Portland street W., and was on view last week, when it was visited by Queen Alexandra and by the Princess Louise. Treatment is entirely free of charge. Every case will be examined by a member of the honorary medical staff, of whom we gave the names in our issue of June 24th. Medical men who have under their care officers who they think would benefit by physical treatment are cordially invited to consult the clinique. A complete installation of whirlpool baths has been presented and the committee and their friends have contributed some £300. It is estimated that a further sum of £3000 is required to meet the initial outlay and cover the rent and running expenses for a period of 12 months. It is specially hoped that a donor may be found for the mechanical apparatus which has cost about £190 and excited a considerable interest among the visitors last week.

BOOKS FOR BRITISH PRISONERS ABROAD.—Regimental care committees and relatives and friends of British prisoners of war will do them a good service by

1 From the Military Analytical Laboratory at Chambery Dr.
A. Hollande.
2 From the laboratory of testing of the Military Hospital Desgenettes
A. Lyons.

A correspondent who is secretly connected with the French Service de Santé of a military hospital in Saver has recently seen a case of creosote poisoning and two of an unusual nature: one from turpentine and one from paraffin. In both cases the victims were not anxious to return to the front line. In other cases of treatable complaint such as influenza and rheumatism he has stayed at home, but has not been in a position definitely to prove it. He needs some roses of the latest method for identifying the poison.

THIRD EXAMINATION FOR THE DEGREE OF BACHELOR OF MEDICINE

Materia Medica Pharmacology and Pharmacology Public Health Medical Jurisprudence Pathology and Elementary Bacteriology—Ewart Gordon Anderson (second-class honours) Wallace Alexander Freedman (second-class honours) John Gilmour (second-class honours) Mary Kathleen Henegan William Arthur Jacques Phyllis Macclott Bertram Sergeant, and William Edward Mandell Wardall

EXAMINATIONS FOR THE LICENCE IN DENTAL SURGERY (L.D.S.)

First Examination Chemistry and Physics—William Alfred Cowden
Second Examination: Dental Mechanics and Dental Metallurgy—Arthur Ernest Murray and Fred Wilkinson
Third Examination Anatomy Physiology and Histology Dental Anatomy Dental Histology and Dental Materia Medica—Wilfred Philipson Spence

THE OXFORD OPHTHALMOLOGICAL CONGRESS—As already announced, this Congress will assemble next Wednesday at Keble College, Oxford, and the two following days will be devoted to addresses and discussion. Ophthalmological instruments and apparatus will be exhibited in the anatomical department of the University Museum. The honorary secretary of the Congress is Mr. Bernard Cridland, Salisbury House, Wolverhampton.

WEST LONDON MEDICO CHIRURGICAL SOCIETY—The annual general meeting of this society will be held at the West London Hospital, Hammersmith, on Friday, July 21st, at 5 P.M., when the annual report of council and the financial statements of the treasurer and of the editorial secretary will be presented and the officers elected for the session 1916-17.

LITERARY INTELLIGENCE—Dr. T. N. Kelynaek is editorially supervising a guide to public and personal service in war time which is to be issued shortly by Messrs. John Bale Sons, and Danielsson under the title of *Pro Patria*. The book will describe the chief organisations and institutions which are engaged in war work, and will include a list of Red Cross hospitals.

THE LONDON INSURANCE COMMITTEE AND ILLEGIBLE PRESCRIPTIONS—One of the cases of complaint against medical men on the London panel investigated by the Medical Service Subcommittee and reported upon to the Insurance Committee at a recent meeting had an element of novelty. The attention of the Subcommittee was called by the father of an insured patient to a prescription furnished by the medical practitioner in question which was also illegible. As a consequence it could not be dispensed and was forwarded to the Committee's office, whence a telegram was sent to the practitioner who eventually rectified the matter. Through this the patient was without medicine for three days. Of the illegibility of the prescription there was no question. The Subcommittee reported that its medical members could not decipher either the name of the patient or of the practitioner nor could they determine any of the drugs which the practitioner wished to be employed. As an explanation he stated that his handwriting was never clear, and that he had either written the prescription in a bad light or his pencil had failed him. He also stated that he constantly suffered from heart attacks which were apt to render his writing worse. The Subcommittee went into the question thoroughly calling for other prescriptions in order to compare them, one of which the practitioner was asked to interpret. He said that it ordered *Lobio Plumbi* but it was found that the druggist who had been asked to make it had read it as *Mistura Senega L.P.* This must have seemed serious enough to the Subcommittee but it was rendered even worse by the practitioner's admission that *Mistura Senega L.P.* was what he had in fact intended the patient to obtain. The prescription which formed the subject of the inquiry he said was for *Mist. Gent. L.P.*, but three gentian mixtures in the London Insurance Pharmacopoeia he said that he meant to order *Mist. Gent. Co.* It was therefore clear that even he could not read his handwriting. As a result the Subcommittee recommended that the medical man should be severely censured and cautioned. It may be noted that the Insurance Committee had ordered the inquiry to be held in spite of the complaint having been withdrawn by those entitled to make it. In the course of its report upon this case the Medical Service Subcommittee made the observation that "medical practitioners should write prescriptions in such a manner as to enable them to be read without difficulty by the chemist or to whom they are presented. It might be added to this that even or careless writing may, either through the delay occasioned or through a misinterpretation on the part of the dispenser, be responsible for serious results and that leaving action for negligence being brought is not one to be despised. In the case under comment the Subcommittee also remarked that it might be "one of the causes of the extraordinary health complaints which he seems to issue from time to time." Here again in addition to the risk to the patient there must needs fairly be danger of serious consequences to the practitioner.

SOUTH LONDON HOSPITAL FOR WOMEN—The new in-patient department of the South London Hospital for Women at 103 South Side Clapham Common, was formally opened by the Queen on Tuesday last, and is expected to be ready for patients in a few weeks' time. The hospital, which was instituted in 1912 as a general hospital for the treatment of women and children, is designed to accommodate 80 patients, and includes paying wards where a fee of £1 1s. to £3 3s. a week will be charged. The general wards are all cross-ventilated single wards, each isolated from atmospheric connexion with any other part of the hospital. Arrangement for open air treatment is secured by forming all roofs as flats and attaching balconies to all the wards. In the wards themselves natural ventilation is relied on, with extract and inlet flues and arrangements for additional electric fans if required later. Both the interior and exterior finish to the entire hospital afford impervious surfaces capable of being washed down. An out-patient department has been in existence at Newington Causeway since April 1913, two houses having been adapted for the purpose. The hospital has been built at the expense of anonymous donors. It is officered entirely by women, the only male employees being the engineer-in-charge and the stoker. The medical staff includes, Mrs. Schalieb, M.D., M.S. (Consulting Surgeon), Miss M. H. Fraser, M.B., B.S. (Physician), Miss M. M. Chadburn, M.D., B.S. (Surgeon), Miss A. M. Roberts, M.D., B.S. (Ophthalmic Surgeon), Miss E. H. Lepper, M.B., B.S., Miss J. Pulteney, M.D., Miss M. G. Thackrah, M.D., B.S. (Assistant Physicians), Miss J. H. Turnbull, M.D., B.S., Miss E. Davies Colley, M.D., F.R.C.S. (Assistant Surgeons), Miss C. Bernard, M.A., L.M.S.S.A. (Radiographer), and Miss G. Brooks, M.B., B.S. (Anaesthetist).

Parliamentary Intelligence.

HOUSE OF COMMONS

WEDNESDAY, JUNE 28TH

Dublin Castle Hospital

Answering Mr. GINNELL, who asked questions about Dublin Castle Hospital, Mr. TENNANT (Under Secretary for War) wrote: The ventilation carried out by nine large windows and two doors is quite ample, irrespective of the height of the ceiling. Daily outdoor exercise for prisoner patients has not been curtailed. Each patient capable of walking gets one hour's exercise daily. The time is deemed sufficient by the visiting medical staff. The hours allotted for visitors to Sinn Féin prisoners have not been restricted and are similar to those allowed for visitors to rounded soldiers. The Sinn Féin prisoners are in every way treated from the point of view of accommodation, medical attendance, and food in exactly the same way as are the wounded soldiers of the British expeditionary forces, for which purpose Dublin Castle Hospital was instituted.

THURSDAY, JUNE 29TH

Sick and Wounded Soldiers

Mr. KING asked the Home Secretary whether during the last two months any more lunatic institutions had been handed over in part or entirely for the accommodation of soldiers or sailors—Mr. BRACE (for Mr. H. SANGUEL) replied: The Northampton County Asylum, Berrywood, and the remainder of the Middlesex County Asylum, Napsbury were handed over for the accommodation of sick and wounded soldiers on April 30th and May 14th respectively.

Mr. KING asked the Under Secretary for War whether it was in contemplation to take over from asylum authorities any further accommodation for uncontrollable nerve-shaken soldiers or sailors who were in consequence to be placed in the Middlesex county asylum, under asylum management—Mr. TENNANT answered: No, Sir.

Consent to Surgical Operations

Mr. CHANCELLOR asked the Under Secretary for War whether a man who had been passed into the army suffering from a disease believed to be curable by a surgical operation could, while in the Army, be forced to undergo such operation without his consent—Mr. TENNANT replied: The man's consent is always obtained before an operation is performed on him.

Mr. SOWDEN: In the case of a minor is the consent of the parent necessary?—Mr. TENNANT: In that case I think recourse would be had to the parents.

Re-examination of Rejected Recruits

Mr. HOGGE asked the Under Secretary for War why the War Office had ordered 300,000 copies of Army Form W 3299, and whether it was their intention to use them in recalling men already rejected on previous occasions as medically unfit, or whether the War Office still adhered to the pledge given by him on May 24th—Mr. TENNANT answered: It is the intention of the War Office to use Army Form W 3299 for the purpose of calling up for re-examination those men

Mr SAMUEL No, it does not apply only for the period of the war. It applies permanently. Continuing, the right honourable gentleman said that the Retrenchment Committee had also reported in favour of the abolition of these reports. He did not know how any Member of the House could support their retention. They were not worth the expenditure that they incurred, and he could not continue to ask the Treasury for the £12,500 per annum which they cost in the existing circumstances.

Sir H CRAIK said he was unwilling to delay a Bill of this kind which was an emergency measure. But he was afraid the arguments of the Home Secretary had not persuaded him that this proposal was justified. He would be the last to oppose any serious proposal for retrenchment, but really they ought to cultivate a sense of proportion. He did not think that the money involved was great enough to induce certifying surgeons to raise an opposition from one end of the country to the other against this proposal. He believed that there were only about 100 surgeons who had anything like considerable pay out of the annual sum of £12,500. About 1900 out of the 2000 surgeons only received mere pittance in fees for the work they did. These were not salaried officers. Certain pay was given for doing certain work. He did not think it was fair to raise a question which had been the subject of dispute for years in an Emergency Bill. In 1901 and 1905 legislation of a similar kind was attempted and had to be abandoned because of the opposition of the working classes. There was not a single representative of the medical profession on the Committee to which the Home Secretary had referred, nor was a single medical witness called before that Committee.

Mr SAMUEL Oh, yes.

Sir H CRAIK said that the certifying surgeons had distinctly informed him that they were not asked to give evidence on the subject. The certifying surgeons considered the professional aspect of the matter as more important than the monetary consideration. They were intimately acquainted with the workers and the accidents to which they were liable, and it was because they wanted to do their best for the workers and had deep sympathy with them in their work that they desired that this part of their work should not be taken away from them. He hoped that the Home Secretary would withdraw the obnoxious clause on the Committee stage.

Mr TOOTILL said that it was very desirable to effect retrenchment in the Departments of the State, but this should not be done where it was likely to interfere with the protection and safeguards, which ought to be strengthened rather than weakened, in reference to the working classes of the country. In taking up this position he was not animated at all by any kind of interest in the certifying surgeons.

Sir P MAGNUS said he did not desire to oppose the second reading of the Bill, and he would reserve his additional arguments in favour of the retention of these duties by the certifying surgeons until the Committee stage.

Mr WALSH said he doubted whether trade unionists all over the country had been aware that this clause was to be forced. For his part he would see that they were put into possession of the facts before the Committee stage.

Mr BRACE (Under Secretary to the Home Department) said he was very surprised at the heat which had been developed in the debate and at the suspicion under which the Home Office lay because of this clause in the Bill. They were introducing this proposal because they held that it was an essential and necessary reform in war time or any other time. In 1914 the total number of accidents notified amounted to 159,413, and the number which were also notified by the certifying surgeons was 52,563 or less than one third of the total accidents. He had examined hundreds of these reports, and in most cases he found them exactly the same as the report which the factory inspector sent in based on information supplied by the employer. If he thought for one moment that the abolition of these reports would introduce danger to the health of life or limb of the factory workers he would not bring forward this proposal. What were needed were more factory inspectors with technical knowledge and if there were to have a higher standard of medical inspection the Home Office would prefer to have full time medical inspectors rather than this system of certifying surgeons which at present existed.

Mr ANFURN WILLIAMS took objection to the proposal to abolish certifying surgeons. The certifying surgeon had important functions to perform and important information to obtain. He often reported on what should be done to prevent similar accidents recurring in the future. There was certainly a small percentage of cases in which further precautions were required. The certifying surgeon was the man on the spot first after the accident and he was the man who saw the patient. It was not mechanical accidents with which these medical men had to deal. They had to deal with chemical and electrical accidents. Who was better able to form an opinion about a man who had been gassed? The certifying surgeon constituted as it were, the sieve through which thousands of accidents passed, and the

inspector judged on the reports whether a visit from him was necessary or not. The substantial services rendered in this respect should not be abolished until there was something to put in their place. It was remarkable that no private Member who had spoken had supported the proposal in the Bill.

Mr BARTLEY DENNIS considered that the economy involved in the abolition of certifying surgeons was very mistaken. This attempt to alter a state of affairs which had prevailed for 70 years was being made at a time when accidents were more frequent than they had been before the war. Inexperience and fatigue were the causes of most of the accidents. There were more dangerous trades at present in operation than before. Yet it was proposed to cut off the certifying surgeon, and at a time when there were not enough factory inspectors.

Mr WHITEHOUSE protested strongly against the abolition of certifying surgeons.

Mr GOLDSTONE remarked that these medical men were a guarantee that accurate reports were sent in by the employers.

Mr H SAMUEL said that he still thought that large numbers of the reports of certifying surgeons were valueless, and he certainly would not have proposed their abolition if he thought that they were useful. The Home Office was retaining the certifying surgeons' work which dealt with certificates of fitness, dangerous trades, and industrial poisoning. He agreed that there was something to be said for certifying surgeons still being used in special cases. There was a desirability of having reports from medical men where it was a case of septic poisoning or of gassing or a case resulting from some deleterious chemical substance. He had contemplated arranging for medical reports in these cases. He had been impressed by the debate, and he was sure that much had been said under misapprehension. He would give further consideration to suggestions which had been made. He would put down an amendment for the Committee stage which he thought would meet the views of some honourable Members, and which while eliminating wasteful expenditure would endeavour to continue the work of the certifying surgeons where even in a limited number of cases it was likely to be useful to the factory inspector, and also in dangerous cases.

The Bill was then read a second time.

WEDNESDAY, JULY 5TH

German and Austrian Medical Men

Mr GEORGE FABER asked the Home Secretary how many German and Austrian medical practitioners, naturalised and enemy aliens respectively, there were at present in this country, and whether any, and if so how many, of either class were interned. Mr HERBERT SAMUEL replied. This information is not available, and could not be obtained without very great labour. The number of German and Austrian medical practitioners left in this country is small, as there was an arrangement for mutual repatriation at the beginning of the war.

Appointments.

Successful applicants for vacancies Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office directed to the Sub Editor not later than 9 o'clock on the Thursday morning of each week such information for gratuitous publication.

HILL, P. E. Colonel A.M.S.T. (Ret.) has been appointed by the Western Command Medical Officer in charge of the German Prisoners Working Camp at Orickhowell.

McMAHON, A. D. M.B. B.Ch. R.U.I. Temporary Tuberculosis Officer for Sunderland.

MURRAY, J. J. M.B. B.Ch. Belf. Dispensary Medical Officer Downpatrick.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

ALTON HANTS. LORD MATOR TRELOAR CRIPPLES HOSPITAL.—Assistant Resident Medical Officer.

BEDFORD COUNTY HOSPITAL.—House Surgeon unmarried Salary as arranged with board &c.

BETHNAL GREEN INFIRMARY.—Medical Superintendent &c Salary &c. approximately £763 per annum.

BIRMINGHAM AND MIDLAND STE. HOSPITAL, Church-street.—Resident Surgeon Salary £200 per annum with board &c.

BIRMINGHAM UNIVERSITY.—Lecturer in Physiological Department Salary £200 per annum.

BOLINGBROOK HOSPITAL, Wandsworth Common S.W.—Resident Medical Officer and House Surgeon Salary £300 per annum and £200 per annum respectively with board &c.

BOLTON INFIRMARY AND DISPENSARY.—Female Third House Surgeon Salary £180 per annum with board &c.

factories and workshops made by certifying surgeons.

Mr HERBERT SAMUEL (Home Secretary) In moving the second reading said that he understood that there was considerable opposition to this clause affecting the position of certifying surgeons. It was not proposed to abolish all the functions of these medical men. They would still be called upon in respect of health work in connexion with children cases of industrial poisoning and the periodical examination of workers in dangerous trades. The only point with which the clause dealt was the abolition of the reports which the certifying surgeons had hitherto made in reference to the deaths or injuries caused to workers by certain classes of accidents. With regard to about one third of the whole number of accidents, the law required that the occupier or some other person in charge of the factory should report both to the factory inspector and the certifying surgeon. The latter made a report stating the nature of the accident and for these reports a sum of £12 500 per annum was paid in fees. The only duty of the certifying surgeon in this regard was to examine the workman and to certify that he had sustained such and such injuries. He had nothing whatever to do with the cause of the accident or how its recurrence could be prevented. What the Home Office really needed in this connexion were not men with medical knowledge but men with mechanical knowledge. These reports made by certifying surgeons were found in practice not to save the factory inspector any work at all but rather to increase the clerical work and to be a hindrance rather than a help. During the course of the year more than 50,000 of these reports were made by certifying surgeons and nearly always they were mere duplicates of the report of the occupier or the factory inspector. He would not dream of requiring in any change in the law which would deal with the safe guarding of the workman. On the contrary he held that it was perfectly possible to make industries more safe. But the point was that they did not want doctors but more fact inspectors. He was with the chemical knowledge. A Special Committee which had been set up in 1911 on this subject had unanimously recommended that these reports were useless duplicates and might as well be abolished. He held that more important than the abolition of the reports was the abolition of the fee paid on the reports. The Transport Workers' Federation had expressed themselves as being in favour of the abolition of the fee paid on the reports. The Transport Workers' Federation had also expressed themselves as being in favour of the abolition of the fee paid on the reports. The Transport Workers' Federation had also expressed themselves as being in favour of the abolition of the fee paid on the reports.

THE CHAIRMAN Does the Bill deal only with the reports and

Mr SAMUEL No, it does not apply only for the period of the war. It applies permanently. Continuing the right honourable gentleman said that the Retrenchment Committee had also reported in favour of the abolition of these reports. He did not know how any Member of the House could support their retention. They were not worth the expenditure that they incurred and he could not continue to ask the Treasury for the £12,500 per annum which they cost in the existing circumstances.

Sir H. CRAIK said he was unwilling to delay a Bill of this kind which was an emergency measure. But he was afraid the arguments of the Home Secretary had not persuaded him that this proposal was justified. He would be the last to oppose any serious proposal for retrenchment, but really they ought to cultivate a sense of proportion. He did not think that the money involved was great enough to induce certifying surgeons to raise an opposition from one end of the country to the other against this proposal. BOLTON INFIRMARY AND DISPENSARY—Female Third House Surgeon. Salary £180 per annum with board &c.

Mr HERBERT SAMUEL (Home Secretary) in moving the second reading said that he understood that there was considerable opposition to this clause affecting the position of certifying surgeons. It was not proposed to abolish all the functions of these medical men. They would still be called upon in respect of health work in connexion with children cases of industrial poisoning and the periodical examination of workers in dangerous trades. The only point with which the clause dealt was the abolition of the reports which certifying surgeons had hitherto made in reference to the deaths or injuries caused to workers by certain classes of accidents. With regard to about one third of the whole number of accidents the law required that the occupier or some other person in charge of the factory should report both to the factory inspector and the certifying surgeon. The latter made a report stating the nature of the accident and for these reports a sum of £12 500 per annum was paid in fees. The only duty of the certifying surgeon in this regard was to examine the workman and to certify that he had sustained such and such injuries. He had nothing whatever to do with the cause of the accident or how its recurrence could be prevented. What the Home Office really needed in this connexion were not men with medical knowledge, but rather men with mechanical knowledge. These reports made by certifying surgeons were found in practice no use save to the factory inspector any work at all, but rather to increase the clerical work and to be a hindrance rather than a help. During the course of the year more than 50,000 of these reports were made by certifying surgeons and nearly always they were mere duplicates of the report of the occupier of the factory. He would not dream of acquiescing in any change in the law which would weaken the safeguards of the worker. On the contrary he held them up as everything possible to make industry more safe. But the point was that he did not want doctors but more factories in possession of technical knowledge. A Special Committee which began its work in 1911 on this subject had unanimously reported that these reports were useless duplicates and a great waste of language to be abolished. He also pointed out that the Government's proposals from the representative bodies of labour, except from some local branches of the Trades Union Congress, were entirely against his proposal. The Trades Union Congress had expressed their own views on the subject in 1916 and in 1917 it came from the ranks of the Labour Party and the Independent Labour Party highly organized and prepared and when asked to take any step which tended to diminish the powers of the certifying surgeon, they refused to do so. In approaching the House of Commons today the Government are not making any suggestion of abolishing the reports of the factory inspectors. The Bill deals only with the reports of

SIR FRANK DOWSON: I think that only one of the reports is

Mr SAMUEL No, it does not apply only for the period of the war. It applies permanently. Continuing the right honourable gentleman said that the Retrenchment Committee had also reported in favour of the abolition of these reports. He did not know how any Member of the House could support their retention. They were not worth the expenditure that they incurred, and he could not continue to ask the Treasury for the £12,500 per annum which they cost in the existing circumstances.

Sir H CRAIK said he was unwilling to delay a Bill of this kind which was an emergency measure. But he was afraid the arguments of the Home Secretary had not persuaded him that this proposal was justified. He would be the last to oppose any serious proposal for retrenchment, but really they ought to cultivate a sense of proportion. He did not think that the money involved was great enough to induce certifying surgeons to raise an opposition from one end of the country to the other against this proposal. He believed that there were only about 100 surgeons who had anything like considerable pay out of the annual sum of £12,500. About 1900 out of the 2000 surgeons only received mere pittance in fees for the work they did. These were not salaried officers. Certain pay was given for doing certain work. He did not think it was fair to raise a question which had been the subject of dispute for years in an Emergency Bill. In 1901 and 1905 legislation of a similar kind was attempted and had to be abandoned because of the opposition of the working classes. The number of German and Austrian medical practitioners left in this country is small, as there was an arrangement for mutual repatriation at the beginning of the war.

Appointments.

Successful applicants for vacancies Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office directed to the Sub-Editor not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

HILL, P. E. Colonel A.M.S.T. (Ret.) has been appointed by the Western Command Medical Officer in charge of the German Prisoners Working Camp at Crickhowell.
McMAHON, A. D. M.B. B.Ch. R.U.I. Temporary Tuberculosis Officer for Sunderland.
MURRAY, J. J. M.B. B.Ch. Belf. Dispensary Medical Officer Downpatrick.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index). When the application of a Belgian medical man would be considered the advertiser is requested to communicate with the Editor.

ALTON HANTS. LORD MAYOR TRELOAR CRIPPLES HOSPITAL—Assistant Resident Medical Officer.
BEDFORD COUNTY HOSPITAL—House Surgeon unmarried Salary as arranged with board &c.
BETHNAL GREEN INFIRMARY—Medical Superintendent &c Salary &c. approximately £763 per annum.
BIRMINGHAM AND MIDLAND EYE HOSPITAL, Church-street.—Resident Surgeon Salary £200 per annum with board &c.
BIRMINGHAM UNIVERSITY—Lecturer in Physiological Department Salary £200 per annum.
BOLINGBROKE HOSPITAL, Wandsworth Common S.W.—Resident Medical Officer and House Surgeon Salary £300 per annum and £200 per annum respectively with board &c.
BOLTON INFIRMARY AND DISPENSARY—Female Third House Surgeon Salary £180 per annum with board &c.

factories and workshops made by certifying surgeons.
Mr HERBERT SAMUEL (Home Secretary) In moving the second reading said that he understood that there was considerable opposition to this clause affecting the position of certifying surgeons. It was not proposed to abolish all the functions of these medical men. They would still be called upon in respect of health work in connexion with children cases of industrial poisoning, and the periodical examination of workers in dangerous trades. The only point with which the clause dealt was the abolition of the reports which certifying surgeons had hitherto made in reference to the deaths or injuries caused to workers by certain classes of accidents. With regard to about one third of the whole number of accidents the law required that the occupier or some other person in charge of the factory should report both to the factory inspector and the certifying surgeon. The latter made a report stating the nature of the accident and for these reports a sum of £12 500 per annum was paid in fees. The only duty of the certifying surgeon in this regard was to examine the workman and to certify that he had sustained such and such injuries. He had nothing whatever to do with the cause of the accident or how its recurrence could be prevented. What the Home Office really needed in this connexion were not men with medical knowledge but rather men with mechanical knowledge. These reports made by certifying surgeons were found in practice not to save the factory inspector any work at all but rather to increase the clerical work and to be a hindrance rather than a help. During the course of the year more than 50,000 of these reports were made by certifying surgeons and nearly always they were mere duplicates of the report of the occupier of the factory. He would not dream of acquiescing in a change in the law which would weaken the safeguards of the worker. On the contrary he held them up as doing what it was possible to make industry more safe. But the point was that they did not want doctors but more factories inspectors with technical knowledge. A Special Committee established in 1911 on his subject had unanimously recommended that these reports were needless duplications and that no advantage be abolished. He believed that the Government against this proposal from being represented by the Labour Party except from some local branches of the Labour Party on the Trade Union Workers' Federation side. He expressed himself strongly against the proposal. It seemed to come from the same old philosophy of "let us have bright examples before us and let us have the best people able to be led by us." The Government must approach the House of Commons. They could not say that there was a great deal of sense in it. It was a very old-fashioned idea to reform things and to put them back again.

Mr H. CLARKE (Dorset) I am glad to see that the Government

Mr SAMUEL No it does not apply only for the period of the war. It applies permanently. Continuing the right honourable gentleman said that the Retrenchment Committee had also reported in favour of the abolition of these reports. He did not know how any Member of the House could support their retention. They were not worth the expenditure that they incurred and he could not continue to ask the Treasury for the £12,500 per annum which they cost in the existing circumstances.

Sir H CRAIK said he was unwilling to delay a Bill of this kind which was an emergency measure. But he was afraid the arguments of the Home Secretary had not persuaded him that this proposal was justified. He would be the last to oppose any serious proposal for retrenchment but really they ought to cultivate a sense of proportion. He did not think that the money involved was great enough to induce certifying surgeons to raise an opposition from one end of the country to the other against this proposal. He believed that there were only about 100 surgeons who had anything like considerable pay out of the annual sum of £12,500. About 1900 out of the 2000 surgeons only received mere pittance in fees for the work they did. These were not salaried officers. Certain pay was given for doing certain work. He did not think it was fair to raise a question which had been the subject of dispute for years in an Emergency Bill. In 1901 and 1905 legislation of a similar kind was attempted and had to be abandoned because of the opposition of the working classes. There was no single representative of the medical profession on the Committee to which the Home Secretary had referred nor was a single medical witness called before that Committee.

Mr SAMUEL Oh, yes.

Sir H CRAIK said that the certifying surgeons had distinctly informed him that they were not asked to give evidence on the subject. The certifying surgeons considered the professional aspect of the matter as more important than the monetary consideration. They were intimately acquainted with the workers and the accidents to which they were liable and it was because they wanted to do their best for the workers and had deep sympathy with them in their work that they desired that this part of their work should not be taken away from them. He hoped that the Home Secretary would withdraw the obnoxious clause on the Committee stage.

Mr TOOTILL said that it was very desirable to effect retrenchment in the Departments of the State, but this should not be done where it was likely to interfere with the protection and safeguards, which ought to be strengthened rather than weakened, in reference to the working classes of the country. In taking up this position he was not animated at all by any kind of interest in the certifying surgeons.

Sir P MAGNUS said he did not desire to oppose the second reading of the Bill, and he would reserve his additional arguments in favour of the retention of these duties by the certifying surgeons until the Committee stage.

Mr WALSH said he doubted whether trade unionists all over the country had been aware that this clause was to be forced. For his part he would see that they were put into possession of the facts before the Committee stage.

Mr BEACE (Under Secretary to the Home Department) said he was very surprised at the heat which had been developed in the debate and at the suspicion under which the Home Office lay because of this clause in the Bill. They were introducing this proposal because they held that it was an essential and necessary reform in war time or any other time. In 1914 the total number of accidents notified amounted to 159,415 and the number which were also notified by the certifying surgeons was 52,553 or less than one-third of the total accidents. He had examined hundreds of these reports and in most cases he found them exactly the same as the report which the factory inspector sent in based on information supplied by the employer. If he thought for one moment that the abolition of these reports would introduce danger to the health of life or limb of the factory workers he would not bring forward this proposal. What were needed were more factory inspectors with technical knowledge and if they were to have a higher standard of medical inspection the Home Office would prefer to have full time medical inspectors rather than this system of certifying surgeons which at present existed.

Mr ANEPYR WILLIAMS took objection to the proposal to abolish certifying surgeons. The certifying surgeon had important functions to perform and important information to obtain. He often reported on what should be done to prevent similar accidents recurring in the future. There was certainly a small percentage of cases in which further precautions were required. The certifying surgeon was the man on the spot first after the accident and he was the man who knew the patient. It was not mechanical accidents which these medical men had to deal. They had to deal with chemical and electrical accidents. Who was better able to form an opinion about a man who had been gassed? The certifying surgeon constituted as it were, the sieve through which thousands of accidents passed and the

inspector judged on the reports whether a visit from him was necessary or not. The substantial services rendered in this respect should not be abolished until there was something to put in their place. It was remarkable that no private Member who had spoken had supported the proposal in the Bill.

Mr BAPTLEY DENNIS considered that the economy involved in the abolition of certifying surgeons was very mistaken. This attempt to alter a state of affairs which had prevailed for 70 years was being made at a time when accidents were more frequent than they had been before the war. Inexperience and fatigue were the causes of most of the accidents. There were more dangerous trades at present in operation than before. Yet it was proposed to cut off the certifying surgeon, and at a time when there were not enough factory inspectors.

Mr WHITEHOUSE protested strongly against the abolition of certifying surgeons.

Mr GOLDSTONE remarked that these medical men were a guarantee that accurate reports were sent in by the employers.

Mr H SAMUEL said that he still thought that large numbers of the reports of certifying surgeons were valueless and he certainly would not have proposed their abolition if he thought that they were useful. The Home Office was retaining the certifying surgeons work which dealt with certificates of fitness dangerous trades and industrial poisoning. He agreed that there was something to be said for certifying surgeons still being used in special cases. There was a desirability of having reports from medical men where it was a case of septic poisoning or of gassing or a case resulting from some deleterious chemical substance. He had contemplated arranging for medical reports in these cases. He had been impressed by the debate, and he was sure that much had been said under misapprehension. He would give further consideration to suggestions which had been made. He would put down an amendment for the Committee stage which he thought would meet the views of some honourable Members and which while eliminating wasteful expenditure would endeavour to continue the work of the certifying surgeons where even in a limited number of cases it was likely to be useful to the factory inspector and also in dangerous cases.

The Bill was then read a second time.

WEDNESDAY JULY 5TH

German and Austrian Medical Men

Mr GEORGE FABER asked the Home Secretary how many German and Austrian medical practitioners, naturalised and enemy aliens respectively, there were at present in this country, and whether any, and if so how many of either class were interned. Mr HERBERT SAMUEL replied. This information is not available, and could not be obtained without very great labour. The number of German and Austrian medical practitioners left in this country is small, as there was an arrangement for mutual repatriation at the beginning of the war.

Appointments.

Successful applicants for vacancies Secretaries of Public Institutions and others possessing information suitable for this column are invited to forward to THE LANCET Office directed to the Editor not later than 9 o'clock on the Thursday morning of each week such information for general publication.

HILL P E Colonel A.M.S.T. (Ret.) has been appointed by the Western Command Medical Officer in charge of the German Prisoners Working Camp at Crickhowell.

McMAHON A D M.B. B.Ch. R.U.I. Temporary Tuberculosis Officer for Sunderland.

MERRAT J J M.B. B.Ch. Belf. Dispensary Medical Officer Downpatrick.

Vacancies.

For further information regarding each vacancy, reference should be made to the advertisement (see Index). When the application of a British medical man would be considered the advertisements are requested to communicate with the Editor.

ALTON HANTS. LORD MAYOR TRELOAR CRIPPLES HOSPITAL—Assistant Resident Medical Officer.

BEDFORD COUNTY HOSPITAL—House Surgeon unmarried. Salary as arranged with board &c.

BIRMINGHAM GREY INFIRMARY—Medical Superintendent &c. Salary approximately £765 per annum.

BOLTON INFIRMARY AND DISPENSARY—Female Third House Surgeon. Salary £150 per annum with board &c.

In the course of the debate on the Home Office Estimates in Committee of Supply Mr BRACE (Under Secretary for the Home Department) said: The troublesome question of a non poisonous dope in aircraft factories is a matter on which the Home Office has been much disturbed. We have had to answer questions in this House in regard to women and men whose lives have been taken because of their having to work this poisonous dope. The dope question affects not only the Home Office but also and more particularly the Admiralty and the War Office. I am glad to be able to say that as a result of communications between the Home Secretary and the Ministers of those two departments we at last see our way to having a non poisonous dope sufficient and efficacious for all purposes for aircraft whether for sea work or for work on land. I am hoping that within a few weeks from now the poisonous dope which has been in use and has been so deadly to the workers will be a thing of the past. The Home Office has been continually pressing for the best ventilation for great precautions and for everything in the shape of precautionary measures but would make work upon poisonous dope less dangerous. But we have felt all along that the real solution of the question was a non poisonous dope. I conceived have been working together and as a result I think the noble Lord who brought forward this question, Lord Henry Cavendish-Bentinck, may take it for certain that within a very short time all this danger will be removed and the workers in our aircraft factories will be able to go about their employment without in any less danger to life and health than has hitherto been the case.

factories and workshops made by certifying surgeons.

Mr HERBERT SAMUEL (Home Secretary). In moving the second reading said that he understood that there was considerable opposition to this clause affecting the position of certifying surgeons. It was not proposed to abolish all the functions of these medical men. They would still be called upon in respect of health work in connexion with children cases of industrial poisoning and the periodical examination of workers in dangerous trades. The only point with which the clause dealt was the abolition of the reports which the certifying surgeons had hitherto made in reference to the deaths or injuries caused to workers by certain classes of accidents. With regard to about one third of the whole number of accidents, the law required that the occupier or some other person in charge of the factory should report both to the factory inspector and the certifying surgeon. The latter made a report stating the nature of the accident and for these reports a sum of £12 500 per annum was paid in fees. The only duty of the certifying surgeon in this regard was to examine the workman and to certify that he had sustained such and such injuries. He had nothing whatever to do with the cause of the accident or how its recurrence could be prevented. What the Home Office really needed in this connexion were not men with medical knowledge but rather men with mechanical knowledge. These reports made by certifying surgeons were found in practice no to save the factory inspector any work at all but rather to increase the clerical work and to be a hindrance rather than a help. During the course of the year more than 50,000 of these reports were made by certifying surgeons and nearly always they were mere duplicates of the report of the occupier of the factory. He would not dream of signing in any case any in the law which would weaken the safe and sound workman. On the contrary he held his own wherever it was possible to make industries more safe. But the point was that they did not want doctors but more fact inspectors with technical knowledge. A Special Committee which began in 1911 on this subject had unanimously recommended that the reports were useless duplicates and might be a disadvantage to abolish them. He had received evidence from the representatives of the employers and the labour except from some local branches of the Trades Union Council. The Transport Workers' Union had also expressed their views clearly but they were not representative of the movement as a whole. He was glad to have the opportunity of expressing his opinion on the matter and to say that he was in favour of abolishing the reports because they were a waste of time and money and because they were a hindrance to the work of the factory inspector. He hoped that the House would agree to the clause.

Sir H. CHURCHILL. Does the Bill deal only with the reports?

Sr H. CHURCHILL. Does the Bill deal only with the reports?

Mr SAMUEL No, it does not apply only for the period of the war. It applies permanently. Continuing the right honourable gentleman said that the Retrenchment Committee had also reported in favour of the abolition of these reports. He did not know how any Member of the House could support their retention. They were not worth the expenditure that they incurred and he could not continue to ask the Treasury for the £12,500 per annum which they cost in the existing circumstances.

Sir H CRAIK said he was unwilling to delay a Bill of this kind which was an emergency measure. But he was afraid the arguments of the Home Secretary had not persuaded him that this proposal was justified. He would be the last to oppose any serious proposal for retrenchment, but really they ought to cultivate a sense of proportion. He did not think that the money involved was great enough to induce certifying surgeons to raise an opposition from one end of the country to the other against this proposal. He believed that there were only about 100 surgeons who had anything like considerable pay out of the annual sum of £12,500. About 1900 out of the 2000 surgeons only received mere pittance in fees for the work they did. These were not salaried officers. Certain pay was given for doing certain work. He did not think it was fair to raise a question which had been the subject of dispute for years in an Emergency Bill. who under the instructions issued are liable to be summoned for medical re-examination. There is no ground for the suggestion that anything inconsistent with what I said on May 24th will be done. It is very difficult to say what number will be called up, and there is no means of ascertaining it.

Exemptions to Dentists

Mr. PACT asked the Under Secretary for War whether he had seen the resolutions passed by the borough of Cambridge deprecating the action of the military authorities in withdrawing dentists from the practice of their profession and putting them to do the work of ordinary soldiers, and what was the policy of the War Office in the matter.—Mr. TENNANT wrote in reply: I have not seen the resolution to which the honourable Member refers. Claims for the exemption of dental surgeons whose services the principal medical officer considers indispensable have been assented to conditionally on their services with the troops being continued. In other cases dentists have recourse to the tribunals in the ordinary way. A decision by the Central Tribunal in a recent case has been circulated to tribunals. In this case the dentist was granted exemption conditionally on his remaining in his present occupation. The following was added: 'The Central Tribunal, from evidence submitted to them, are impressed with the danger of further reducing the number of registered dentists now in this country. Whether any particular dentist should be granted exemption must obviously depend to some extent upon the requirements of the place in which he practises, but they are inclined to think that unless it be shown that his services are not required, he should be granted exemption. Similar considerations apply to the mechanics on whom dentists depend for the efficient performance of their work.'

Treatment of Tuberculosis in Poor houses

Mr. CURRIE asked the representative of the National Insurance Commissioners whether the practice which at one time caused dissatisfaction in Scotland of treating tuberculosis cases in poor houses was now entirely forbidden as regards both soldiers and civilians; and whether the public might rely upon no reversion to this practice being permitted.—Mr. CHARLES ROBERTS said in reply: No such arrangement as is indicated in the question can be made by insurance committees under the National Insurance Acts. If the honourable Member will furnish me with further information as to any specific case which he may have in mind, I shall be glad to make inquiry.

Work of the Board of Control

Mr. KING asked the Under Secretary for the Home Department whether the five Lunacy Commissioners now employed entirely on lunacy work were found sufficient for all the requirements of the Lunacy Acts seeing that 14,000 beds had now been removed from lunacy jurisdiction.—Mr. BRACE answered: The work of the Board of Control has been carried out by the Commissioners working long hours, and at the expense of their usual vacation by the assistance given to them by one of the honorary Commissioners and by special arrangement of their work of a temporary nature.

MONDAY, JULY 3RD

Nervous Cases in the Navy

Answering Commander BRILLIANT, who asked questions about the measures being taken to deal with cases of accidental and nervous breakdown in the navy, Mr. MACANULTY (Secretary to the Admiralty) wrote: The treatment of all cases of mental and nervous breakdown is undertaken in the three large base naval hospitals at Chatham, Haslar, and Plymouth. A medical officer who has made a speciality of such cases is detailed to each hospital and he has so many beds allotted to him as is necessary. The treatment adopted is not to collect these cases in one ward or one building but to separate them from each other, as far as possible, treating them with other general cases of illness. So far this method of treatment has been followed by favourable results, but the number of cases of this type from the Fleet is not sufficiently large to enable more than a probable estimate of its value to be formed as yet. Later on it is hoped a detailed report of the results obtained will be of value.

Time expired Men of the Royal Army Medical Corps

Mr. WATT asked the Under Secretary for War whether he was aware that time-expired men of the Royal Army Medical Corps on offering themselves for re-enlistment were being told that they could not be reinstated in that corps, and were being relegated to rifle battalions, would he say whether this was done with the sanction and concurrence of his department, and why, in the interests of economy the training of such men was not utilised.—Mr. TENNANT answered: It would be in accordance with the principle which has been frequently urged in this House that any single man in the Royal Army Medical Corps fit for general service should be transferred to the infantry to make way for the older married men who would rightly be given a preference as regards less exposed service. Such transfers would not of course be made if they involved dislocation of the service from which the transfer was made.

TUESDAY, JULY 4TH

Proposed Abolition of Certifying Surgeons

The House considered on second reading the Police &c (Miscellaneous Provisions) Bill, one of the clauses of which proposes to abolish the system of reports on accidents in factories and workshops made by certifying surgeons.

Mr. HERBERT SAMUEL (Home Secretary) in moving the second reading said that he understood that there was considerable opposition to this clause affecting the position of certifying surgeons. It was not proposed to abolish all the functions of these medical men. They would still be called upon in respect of health work in connexion with children, cases of industrial poisoning, and the periodical examination of workers in dangerous trades. The only point with which the clause dealt was the abolition of the reports which the certifying surgeons had hitherto made in reference to the deaths or injuries caused to workers by certain classes of accidents. With regard to about one third of the whole number of accidents the law required that the occupier or some other person in charge of the factory should report both to the factory inspector and the certifying surgeon. The latter made a report stating the nature of the accident and for these reports a sum of £12,500 per annum was paid in fees.

Mr SAMUEL No, it does not apply only for the period of the war. It applies permanently. Continuing the right honourable gentleman said that the Retrenchment Committee had also reported in favour of the abolition of these reports. He did not know how any Member of the House could support their retention. They were not worth the expenditure that they incurred, and he could not continue to ask the Treasury for the £12,500 per annum which they cost in the existing circumstances.

Sir H CRAIK said he was unwilling to delay a Bill of this kind which was an emergency measure. But he was afraid the arguments of the Home Secretary had not persuaded him that this proposal was justified. He would be the last to oppose any serious proposal for retrenchment, but really they ought to cultivate a sense of proportion. He did not think that the money involved was great enough to induce certifying surgeons to raise an opposition from one end of the country to the other against this proposal. He believed that there were only about 100 surgeons who had anything like considerable pay out of the annual sum of £12,500. About 1900 out of the 2000 surgeons only received mere pittance in fees for the work they did. These were not salaried officers. Certain pay was given for doing certain work. He did not think it was fair to raise a question which had been the subject of dispute for years in an Emergency Bill. In 1901 and 1905 legislation of a similar kind was attempted and had to be abandoned because of the opposition of the working classes. There was not a single representative of the medical profession on the Committee to which the Home Secretary had referred, nor was a single medical witness called before that Committee.

Mr SAMUEL Oh, yes.

Sir H CRAIK said that the certifying surgeons had distinctly informed him that they were not asked to give evidence on the subject. The certifying surgeons considered the professional aspect of the matter as more important than the monetary consideration. They were intimately acquainted with the workers and the accidents to which they were liable, and it was because they wanted to do their best for the workers and had deep sympathy with them in their work that they desired that this part of their work should not be taken away from them. He hoped that the Home Secretary would withdraw the obnoxious clause on the Committee stage.

Mr TOOTILL said that it was very desirable to effect retrenchment in the Departments of the State, but this should not be done where it was likely to interfere with the protection and safeguards, which ought to be strengthened rather than weakened, in reference to the working classes of the country. In taking up this position he was not animated at all by any kind of interest in the certifying surgeons.

Sir P MAGNUS said he did not desire to oppose the second reading of the Bill, and he would reserve his additional arguments in favour of the retention of these duties by the certifying surgeons until the Committee stage.

Mr WALSH said he doubted whether trade unionists all over the country had been aware that this clause was to be forced. For his part he would see that they were put into possession of the facts before the Committee stage.

Mr BRACE (Under Secretary to the Home Department) said he was very surprised at the heat which had been developed in the debate and at the suspicion under which the Home Office lay because of this clause in the Bill. They were introducing this proposal because they held that it was an essential and necessary reform in war time or any other time. In 1914 the total number of accidents notified amounted to 159,413 and the number which were also notified by the certifying surgeons was 52,563 or less than one third of the total accidents. He had examined hundreds of these reports, and in most cases he found them exactly the same as the report which the factory inspector sent in based on information supplied by the employer. If he thought for one moment that the abolition of these reports would introduce danger to the health of life or limb of the factory workers he would not bring forward this proposal. What were needed were more factory inspectors with technical knowledge and if they were to have a higher standard of medical inspection the Home Office would prefer to have full time medical inspectors rather than this system of certifying surgeons which at present existed.

Mr ANEURY WILLIAMS took objection to the proposal to abolish certifying surgeons. The certifying surgeon had important functions to perform and important information to obtain. He often reported on what should be done to prevent similar accidents recurring in the future. There was certainly a small percentage of cases in which further precautions were required. The certifying surgeon was the man on the spot first after the accident and he was the man who saw the patient. It was not mechanical accidents with which these medical men had to deal. They had to deal with chemical and electrical accidents. Who was better able to form an opinion about a man who had been gassed? The certifying surgeon constituted, as it were, the sieve through which thousands of accidents passed, and the

inspector judged on the reports whether a visit from him was necessary or not. The substantial services rendered in this respect should not be abolished until there was something to put in their place. It was remarkable that no private Member who had spoken had supported the proposal in the Bill.

Mr BARTLEY DENNISS considered that the economy involved in the abolition of certifying surgeons was very mistaken. This attempt to alter a state of affairs which had prevailed for 70 years was being made at a time when accidents were more frequent than they had been before the war. Inexperience and fatigue were the causes of most of the accidents. There were more dangerous trades at present in operation than before. Yet it was proposed to cut off the certifying surgeon, and at a time when there were not enough factory inspectors.

Mr WHITEHOUSE protested strongly against the abolition of certifying surgeons.

Mr GOLDSTONE remarked that these medical men were a guarantee that accurate reports were sent in by the employers.

Mr H SAMUEL said that he still thought that large numbers of the reports of certifying surgeons were valueless, and he certainly would not have proposed their abolition if he thought that they were useful. The Home Office was retaining the certifying surgeons' work which dealt with certificates of fitness, dangerous trades, and industrial poisoning. He agreed that there was something to be said for certifying surgeons still being used in special cases. There was a desirability of having reports from medical men where it was a case of septic poisoning or of gassing or a case resulting from some deleterious chemical substance. He had contemplated arranging for medical reports in these cases. He had been impressed by the debate, and he was sure that much had been said under misapprehension. He would give further consideration to suggestions which had been made. He would put down an amendment for the Committee stage which he thought would meet the views of some honourable Members, and which while eliminating wasteful expenditure would endeavour to continue the work of the certifying surgeons where even in a limited number of cases it was likely to be useful to the factory inspector, and also in dangerous cases.

The Bill was then read a second time.

WEDNESDAY, JULY 5TH

German and Austrian Medical Men

Mr GEORGE FABER asked the Home Secretary how many German and Austrian medical practitioners, naturalised and enemy aliens respectively, there were at present in this country, and whether any, and if so how many, of either class were interned. Mr HERBERT SAMUEL replied. This information is not available, and could not be obtained without very great labour. The number of German and Austrian medical practitioners left in this country is small, as there was an arrangement for mutual repatriation at the beginning of the war.

Appointments.

Successful applicants for vacancies Secretaries of Public Institutions and others possessing information suitable for this column, are invited to forward to THE LANCET Office directed to the Sub-Editor not later than 9 o'clock on the Thursday morning of each week such information for gratuitous publication.

HILL, P. E. Colonel A.M.S.T. (Ret.) has been appointed by the Western Command Medical Officer in charge of the German Prisoners Working Camp at Orickhowell.
McMAHON, A. D. M.B. B.Ch. R.U.I. Temporary Tuberculosis Officer for Sunderland.
MURRAY, J. J. M.B. B.Ch. Belf. Dispensary Medical Officer Downpatrick.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index). When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

ALTON HANTS. LORD MAYOR TRELGAR CRIPPLES HOSPITAL—Assistant Resident Medical Officer.
BEDFORD COUNTY HOSPITAL—House Surgeon unmarried Salary as arranged with board &c.
BETHVAL GREEN INFIRMARY—Medical Superintendent &c Salary &c approximately £763 per annum.
BIRMINGHAM AND MIDLAND EYE HOSPITAL, Church-street—Resident Surgeon Salary £200 per annum with board &c.
BIRMINGHAM UNIVERSITY—Lecturer in Physiological Department Salary £200 per annum.
BOLINGBROOK HOSPITAL, Wandsworth Common S.W.—Resident Medical Officer and House Surgeon Salary £300 per annum and £200 per annum respectively with board &c.
BOLTON INFIRMARY AND DISPENSARY—Female Third House Surgeon Salary £180 per annum with board &c.

who under the instructions issued are liable to be summoned for medical re-examination. There is no ground for the suggestion that anything inconsistent with what I said on May 24th will be done. It is very difficult to say what number will be called up, and there is no means of ascertaining it.

Exemptions to Dentists

Mr PACET asked the Under Secretary for War whether he had seen the resolutions passed by the borough of Cambridge deprecating the action of the military authorities in withdrawing dentists from the practice of their profession and putting them to do the work of ordinary soldiers, and what was the policy of the War Office in the matter.—Mr TENNANT wrote in reply: I have not seen the resolution to which the honourable Member refers. Claims for the exemption of dental surgeons whose services the principal medical officer considers indispensable have been assented to conditionally on their services with the troops being continued. In other cases dentists have recourse to the tribunals in the ordinary way. A decision by the Central Tribunal in a recent case has been circulated to tribunals. In this case the dentist was granted exemption conditionally on his remaining in his present occupation. The following was added: "The Central Tribunal, from evidence submitted to them, are impressed with the danger of further reducing the number of registered dentists now in this country. Whether any particular dentist should be granted exemption must obviously depend to some extent upon the requirements of the place in which he practises, but they are inclined to think that unless it be shown that his services are not required, he should be granted exemption. Similar considerations apply to the mechanics on whom dentists depend for the efficient performance of their work."

Treatment of Tuberculosis in Poor houses

Mr CURRIE asked the representative of the National Insurance Commissioners whether the practice which at one time caused dissatisfaction in Scotland of treating tuberculosis cases in poor houses was now entirely forbidden as regards both soldiers and civilians; and whether the public might rely upon no reversion to this practice being permitted.—Mr CHARLES ROBERTS said in reply: No such arrangement as is indicated in the question can be made by insurance committees under the National Insurance Acts. If the honourable Member will furnish me with further information as to any specific case which he may have in mind, I shall be glad to make inquiry.

Work of the Board of Control

Mr KING asked the Under Secretary for the Home Department whether the five Lunacy Commissioners now employed entirely on lunacy work were found sufficient for all the requirements of the Lunacy Acts seeing that 14,000 beds had now been removed from lunacy jurisdiction.—Mr BRACE answered: The work of the Board of Control has been carried out by the Commissioners working long hours, and at the expense of their usual vacation by the assistance given to them by one of the honorary Commissioners, and by special arrangement of their work of a temporary nature.

Mr KING: In any further reduction will it be observed that at least the legal members of that Commission or the Board of Control will not be reduced in their capabilities and numbers?—Mr BRACE: I think that the honourable Member may depend upon the Home Office doing that.

Non-poisonous Dipe in Aircraft Factories

In the course of the debate on the Home Office Estimates in Committee of Supply, Mr BRACE (Under Secretary for the Home Department) said: The troublesome question of a

MONDAY, JULY 3RD

Accident Cases in the Navy

Answering Commander BILLIAMS, who asked questions about the measures being taken to deal with cases of accidental and nervous breakdown in the navy, Mr MACDONALD (Secretary to the Admiralty) wrote: The treatment of all cases of mental and nervous breakdown is undertaken in the three large base naval hospitals at Chatham, Haslar, and Plymouth. A medical officer who has made a specialty of such cases is detailed to each hospital and he has as many beds allotted to him as is necessary. The treatment adopted is not to collect these cases in one ward or one building but to separate them from each other as far as possible and treating them with other general cases of illness. So far this method of treatment has been followed by favourable results, but the number of cases of this type from the Fleet is not sufficiently large to enable more than a probable estimate of its value to be formed as yet. Later on it is hoped a detailed report of the results obtained will be of value.

Time-expired Men of the Royal Army Medical Corps

Mr WATT asked the Under Secretary for War whether he was aware that time expired men of the Royal Army Medical Corps on offering themselves for re-enlistment were being told that they could not be reinstated in that corps, and were being relegated to rifle battalions, would he say whether this was done with the sanction and concurrence of his department, and why, in the interests of economy, the training of such men was not utilised.—Mr TENNANT answered: It would be in accordance with the principle which has been frequently urged in this House that any single man in the Royal Army Medical Corps fit for general service should be transferred to the infantry to make way for the older married men who would rightly be given a preference as regards less exposed service. Such transfers would not of course be made if they involved dislocation of the service from which the transfer was made.

TUESDAY, JULY 4TH

Proposed Abolition of Certifying Surgeons

The House considered on second reading the Police &c (Miscellaneous Provisions) Bill, one of the clauses of which proposes to abolish the system of reports on accidents in factories and workshops made by certifying surgeons.

Mr HERBERT SAMUEL (Home Secretary) in moving the second reading, said that he understood that there was considerable opposition to this clause affecting the position of certifying surgeons. It was not proposed to abolish all the functions of these medical men. They would still be called upon in respect of health work in connexion with children, cases of industrial poisoning, and the periodical examination of workers in dangerous trades. The only point with which the clause dealt was the abolition of the reports which the certifying surgeons had hitherto made in reference to the deaths or injuries caused to workers by certain classes of accidents. With regard to about one third of the whole number of accidents the law required that the occupier or some other person in charge of the factory should report both to the factory inspector and the certifying surgeon. The latter made a report stating the nature of the accident and for these reports a sum of £12,500 per annum was paid in fees. The only duty of the certifying surgeon in this regard was to examine the workman and to certify that he had sustained such and such injuries. He had nothing whatever to do with the cause of the accident or how its recurrence could be prevented. What the Home Office really needed in this connexion were not men with medical knowledge but rather men with mechanical knowledge. These reports made by

Mr SAMUEL No, it does not apply only for the period of the war. It applies permanently. Continuing the right honourable gentleman said that the Retrenchment Committee had also reported in favour of the abolition of these reports. He did not know how any Member of the House could support their retention. They were not worth the expenditure that they incurred and he could not continue to ask the Treasury for the £12,500 per annum which they cost in the existing circumstances.

Sir H. CRAIK said he was unwilling to delay a Bill of this kind which was an emergency measure. But he was afraid the arguments of the Home Secretary had not persuaded him that this proposal was justified. He would be the last to oppose any serious proposal for retrenchment but really they ought to cultivate a sense of proportion. He did not think that the money involved was great enough to induce certifying surgeons to raise an opposition from one end of the country to the other against this proposal. He believed that there were only about 100 surgeons who had anything like considerable pay out of the annual sum of £12,500. About 1900 out of the 2000 surgeons only received mere pittance in fees for the work they did. These were not salaried officers. Certain pay was given for doing certain work. He did not think it was fair to raise a question which had been the subject of dispute for years in an Emergency Bill. In 1901 and 1905 legislation of a similar kind was attempted and had to be abandoned because of the opposition of the working classes. There was not a single representative of the medical profession on the Committee to which the Home Secretary had referred, nor was a single medical witness called before that Committee.

Mr SAMUEL Oh, yes.

Sir H. CRAIK said that the certifying surgeons had distinctly informed him that they were not asked to give evidence on the subject. The certifying surgeons considered the professional aspect of the matter as more important than the monetary consideration. They were intimately acquainted with the workers and the accidents to which they were liable, and it was because they wanted to do their best for the workers and had deep sympathy with them in their work that they desired that this part of their work should not be taken away from them. He hoped that the Home Secretary would withdraw the obnoxious clause on the Committee stage.

Mr TOTTILL said that it was very desirable to effect retrenchment in the Departments of the State, but this should not be done where it was likely to interfere with the protection and safeguards, which ought to be strengthened rather than weakened in reference to the working classes of the country. In taking up this position he was not animated at all by any kind of interest in the certifying surgeons.

Sir P. MAGNUS said he did not desire to oppose the second reading of the Bill, and he would reserve his additional arguments in favour of the retention of these duties by the certifying surgeons until the Committee stage.

Mr WALSH said he doubted whether trade unionists all over the country had been aware that this clause was to be forced. For his part he would see that they were put into possession of the facts before the Committee stage.

Mr BRACE (Under Secretary to the Home Department) said he was very surprised at the heat which had been developed in the debate and at the suspicion under which the Home Office lay because of this clause in the Bill. They were introducing this proposal because they held that it was an essential and necessary reform in war time or any other time. In 1914 the total number of accidents notified amounted to 159,413 and the number which were also notified by the certifying surgeons was 52,563 or less than one-third of the total accidents. He had examined hundreds of these reports and in most cases he found them exactly the same as the report which the factory inspector sent in based on information supplied by the employer. If he thought for one moment that the abolition of these reports would introduce danger to the health of life or limb of the factory workers he would not bring forward this proposal. What were needed were more factory inspectors with technical knowledge and if they were to have a higher standard of medical inspection the Home Office would prefer to have full time medical inspectors rather than this system of certifying surgeons which at present existed.

Mr ASQUITH WILLIAMS took objection to the proposal to abolish certifying surgeons. The certifying surgeon had important functions to perform and important information to obtain. He often reported on what should be done to prevent similar accidents recurring in the future. There was certainly a small percentage of cases in which further precautions were required. The certifying surgeon was the man on the spot first after the accident and he was the man who saw the patient. It was no mechanical accidents with which these medical men had to deal. They had to deal with chemical and electrical accidents. Who was better able to form an opinion about a man who had been gassed? The certifying surgeon constituted, as it were, the sieve through which thousands of accidents passed and the

inspector judged on the reports whether a visit from him was necessary or not. The substantial services rendered in this respect should not be abolished until there was some thing to put in their place. It was remarkable that no private Member who had spoken had supported the proposal in the Bill.

Mr BARTLEY DENNISS considered that the economy involved in the abolition of certifying surgeons was very mistaken. This attempt to alter a state of affairs which had prevailed for 70 years was being made at a time when accidents were more frequent than they had been before the war. Inexperience and fatigue were the causes of most of the accidents. There were more dangerous trades at present in operation than before. Yet it was proposed to cut off the certifying surgeon, and at a time when there were not enough factory inspectors.

Mr WHITEHOUSE protested strongly against the abolition of certifying surgeons.

Mr GOLDSTONE remarked that these medical men were a guarantee that accurate reports were sent in by the employers.

Mr H. SAMUEL said that he still thought that large numbers of the reports of certifying surgeons were valueless, and he certainly would not have proposed their abolition if he thought that they were useful. The Home Office was retaining the certifying surgeons' work which dealt with certificates of fitness, dangerous trades, and industrial poisoning. He agreed that there was something to be said for certifying surgeons still being used in special cases. There was a desirability of having reports from medical men where it was a case of septic poisoning or of gassing or a case resulting from some deleterious chemical substance. THE PRIVATE REMOVAL OF SICK OR WOUNDED FROM ABROAD

To the Editor of THE LANCET

SIR—A sick or wounded man lying in a military hospital abroad may have friends who would be glad to let him home themselves or they might like to depute the mission to a medical man, rather than await the invalid's arrival at a hospital convey.

Is it permissible for a civilian to visit a patient at a military hospital abroad, and possible to obtain the consent of the authorities to the man's removal as an ordinary traveller?

I am, Sir, yours faithfully

July 3rd, 1916

V D

* Every case would entail a separate application for permission and freedom of travel is necessarily abolished for civilians.—ED L

A DISTINCTIVE MEDICINE BOTTLE

If only for the reason that it emphasises a need we welcome any invention that has for its object the prevention of deaths by accidental poisoning where the victim has taken the poison in mistake for medicine. Mr W F Hills of 12, Marine terrace Margate has submitted to us a device consisting of a sheath, made to fit any shaped bottle on which is a clock dial with movable hands. An annular opening at the base of one of the hands indicates the interval, in hours, at which the medicine is to be given while the hands can be set for the time at which the next dose is to be taken. The inventor contends that if medicines were always kept in such a sheath-covered bottle it would amount to criminal negligence if accident occurred when they were given from any other kind of bottle. Owing to the surface of the sheath, he adds and its general physical properties being in sharp contrast to those of a glass bottle, the medicine bottle would be recognisable instantly by touch and could be found in the dark. That the device costs little to manufacture is a real argument in its favour otherwise it possesses no advantages over other contrivances with a similar object. The specimen sheath sent to us is made of celluloid and ordinary celluloid paraphernalia should not be multiplied in the sick room.

If only for the reason that it emphasises a need, we welcome any invention that has for its object the prevention of deaths by accidental poisoning where the victim has taken the poison in mistake for medicine. Mr. W. F. Hills of 12, Marine terrace Margate has submitted to us a device consisting of a sheath, made to fit any shaped bottle on which is a clock dial with movable hands. An annular opening at the base of one of the hands indicates the interval, in hours, at which the medicine is to be given while the hands can be set for the time at which the next dose is to be taken. The inventor contends that if medicines were always kept in such a sheath-covered bottle it would amount to criminal negligence if accident occurred when they were given from any other kind of bottle. Owing to the surface of the sheath, he adds and its general physical properties being in sharp contrast to those of a glass bottle, the medicine bottle would be recognisable instantly by touch and could be found in the dark. The device costs little to manufacture is a real argument in its favour otherwise it possesses no advantages over other contrivances with a similar object. The specimen submitted to us is made of celluloid and ordinary celluloid paraphernalia should not be multiplied in the sick room.

NECESSITOUS LADIES HOLIDAY FUND

To the Editor of THE LANCET

SIR—Much self-sacrificing help has been given to other charities to meet the needs this awful war has involved with the poor ladies are likely to be overlooked and yet no one has suffered so pitifully as the poorer gentry through loss of work and therefore of money.

Any contributions sent to me at this address will be thankfully acknowledged and distributed.

I am, Sir, your obedient servant

43 Upper Berkeley street London W. June 30th 1916

THE DESTRUCTION OF COCHIABAM

To the Editor of THE LANCET

SIR—With reference to recent correspondence in your columns on this subject, I call the attention of your readers to a book "Some New and Future Shipping Lines" by Dr. W. Melville Davis, a naval superintendent of the Porth Steamship Company, Ltd., and recently published by John Wiley and Sons, Limited. It deals with various proposed lines which are now being given their life by the naval authorities in connection with our war effort and is one of the best in my collection. I am, Sir, yours faithfully

EDITORIAL NOTICES

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR" and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication. We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor." Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES

THE INDEX AND TITLE-PAGE TO THE LANCET.

January to June, 1916

In view of the Government restrictions upon the supply of paper and the shortage of paper quite apart from these restrictions, the Index and the Title-page to the volume of THE LANCET which was completed with the issue of June 24th have been printed separately, and copies are being supplied gratis to those subscribers who have already intimated to us their wish to receive them. Other subscribers will be similarly supplied so long as the stock remains unexhausted, on application to the Manager THE LANCET Office, 423, Strand, London, W.C. Such application should please be sent in at once.

Volumes and Cases

VOLUMES for the first half of the year 1916 will be ready shortly. Bound in cloth, gilt lettered price 16s, carriage extra.

Cases for binding the half year's numbers are now ready. Cloth gilt lettered, price 2s, by post 2s 4d. To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices 423 Strand London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices and consequently inquiries concerning missing copies, &c. should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

A DISTINCTIVE MEDICINE BOTTLE

If only for the reason that it emphasises a need we welcome any invention that has for its object the prevention of deaths by accidental poisoning where the victim has taken the poison in mistake for medicine. Mr W F Hills of 12, Marine terrace Margate has submitted to us a device consisting of a sheath, made to fit any shaped bottle on which is a clock dial with movable hands. An annular opening at the base of one of the hands indicates the interval, in hours at which the medicine is to be given while the hands can be set for the time at which the next dose is to be taken. The inventor contends that if medicines were always kept in such a sheath-covered bottle it would amount to criminal negligence if accident occurred when they were given from any other kind of bottle. Owing to the surface of the sheath, he adds and its general physical properties being in sharp contrast to those of a glass bottle the medicine bottle would be recognised instantly by touch and could be found in the dark. That the device costs little to manufacture is a real argument in its favour otherwise it possesses no advantage over other contrivances with a similar object. The specimen sheath sent to us is made of celluloid and ordinary celluloid paraphernalia should not be multiplied in the sick room.

SECTION I.—SINUSES AND SINUS FORMATION

Scope of Inquiry

AN attempt has been made to study the bacteriological flora of the wounds from the moment of admission to hospital and subsequently through the various stages of the illness, correlating the bacteriological knowledge with the clinical symptoms, surgical treatment, and sequelae. The condition of the blood was also studied in relation to the degree and variety of sepsis and particular attention given to the benefit or otherwise of the use of bacterial vaccines. As the inquiry progressed certain other problems related to the persistence of unhealed wounds with sinus formation and the appearance of general disturbance with secondary attacks of fever and inflammation often associated with trivial surgical interference with the wound, demanded special attention. The inquiry is divided into three main lines of research necessitating a division of the report into three sections, mutually interdependent—namely, (1) Sinuses and sinus formation, (2) Vaccine therapy and wound infection, (3) General tissue reactions in wound infection.

The following schedule indicates the scheme by which the data of the report were obtained.

1 *Bacterial flora and clinical symptoms of various degrees of injury* which have been classified as far as is possible to do so into four classes (a) Simple flesh wounds (b) Flesh wounds with considerable damage and bruising to the soft parts but without definite bone injury, as determined by radiographic examination (c) Wounds with bone injury, compound comminuted fractures, &c. (d) Wounds involving joints with or without fracture of bone, abdominal wounds, skull and spinal wounds.

2 *A critical inquiry into the use of bacterial vaccines as an adjunct to other methods of treatment*—The cases for this part of the investigation were selected in pairs conforming to the four classes noted above. One case was given vaccine treatment and the other retained as a control. As far as possible cases from the same convicts were selected wounded on or about the same date and treated in the same ward under the same medical officer and general surgical procedure. When this was not possible great care was exercised to select cases with similar surgical conditions and subjected to the same treatment. The clinical history of the cases was carefully followed from the records kept in the wards, temperature charts, &c.

3 *Alteration in the blood in cases of wound infection* relating both to the corpuscular elements and the serum. Several points of diagnostic and prognostic importance have been studied and will be subsequently dealt with.

4 *The bacterial flora of sinuses and the bacterial factors in so-called 'flares' following secondary operations*. Many of the cases originally examined in the base hospital are transferred to an auxiliary hospital and are readmitted to the base hospital for further surgical treatment or for medical boards. The presence of sinuses and sequestra in many of these cases called for special attention and several important facts bearing on treatment have come to light and as the observations have extended over a considerable time the cases are representative of the general types of wound infection.

Bacteriological Methods

As the routine methods in use have been the same throughout the whole of my investigations a preliminary epitome of them will be given.

No. 2-5

In every case films of the pus were examined microscopically stained by Gram's stain counterstained with dilute carbol fuchsin. In some instances further films were examined with Giemsa's stain and Wright's capsule stain.

Cultural Methods

The material (pus or other discharge) was collected before the wound was dressed by means of a sterile swab on a long stout wire, enabling the depth of the wound to be examined. In the case of closed cavities, sequestra, &c. a swab of the surgeon's wound was obtained before the cavity was entered and subsequently from the depth of the cavity, avoiding the external part of the wound. Portions of bone from sequestra, callus, pieces of muscle, and other tissue were also examined and a portion further submitted to histological examination. The material so obtained was inoculated on to the following media (1) egg broth, (2) glucose formate broth, (3) minced autoclaved meat, (4) autoclaved milk, (5) gelatin. The milk, egg broth, and meat were heated and a layer of liquid paraffin poured on. For the sowings the original material was suspended in broth and inoculated (1) into the egg broth without previous heating, (2) heated to 60° C for 15 minutes and sown in milk, (3) heated to 80° C for 5 minutes and sown in meat, (4) on to the gelatin and glucose formate broth without heating. If plenty of the original material is present in the broth emulsion before sowing, especially blood and bits of tissue, the paraffin method was found to be reliable, and has rarely failed to give a good growth of all the organisms seen in the pus films. The results compared very favourably with those obtained by the anaerobic jar method, and the process is economical with regard to space. Subcultures on to paraffin covered media are not so satisfactory, and further subcultures and plates were treated in the anaerobic jar.

Preparations of the egg broth and glucose formate broth, meat and milk at 24-48 hours were stained by Gram and counterstained with carbol fuchsin, hanging-drop preparations were also examined when indicated. By these means an early general diagnosis is possible in 24-48 hours. The smear preparation can be used for provisional diagnosis. Thus a film showing Gram positive bacilli with no spores and the organisms surrounded by a capsule is evidence of infection with *B. perfringens*. Spore-forming Gram-positive bacilli with clostridial and subterminal spore formation indicate bacilli of the malignant oedema group, or of *B. Rodella III*. (Hibler IX.)

The further diagnosis is completed by examination of the cultures and film* &c., of the 48 hours growth thus—

Egg-broth—Cocci (streptococci, staphylococci), *B. proteus*, and *B. malignant oedema* produce a thick flocculent precipitate, when malignant oedema is present there may be black staining. *B. perfringens* alone produces no precipitation of egg broth. Evil putrefactive smell is caused by the malignant oedema group and *B. Hibler* groups not by *B. perfringens*, the latter only causing a butyric smell.

Milk—*B. perfringens* produces a "stormy clot"—i.e., acid with evolution of gas which causes the clot to be broken up, it often adheres in torn fragments to the side of the tube and considerable contraction, at first suggesting peptonisation, occurs but no subsequent digestion of the clot takes place. Streptococci and staphylococci produce acid and occasionally clotting, no digestion. *B. malignant oedema* does not affect the milk in 24 hours and in the presence of rapidly growing *perfringens* not at all. Alone and in combination with *B. perfringens* digestion occurs slowly. Hibler IX. (*Rodella III*) has a very slow peptonising effect.

Meat—Streptococci and staphylococci have no marked action. *B. perfringens* group causes a red colouration peptonisation and gas formation, and a smell of butyric acid but no putrefactive odour. Malignant oedema and *B. Hibler* produce peptonisation, malignant oedema blackening, isolated black patches in a reddish brown matrix are often seen, indicating *B. perfringens* and malignant oedema. Both malignant oedema and *B. Hibler* evolve putrid gases.

Glucose formate broth—Aerobic coli and proteus group, staphylococci may be observed gas formation in the coll or the prote grow feebly on this the egg broth group streptococci met with anaerobes. *B. per* belonging to the eptococci may nce of either on the wound on found on the class of facultative hen many

An Inquiry

INTO

THE NATURAL HISTORY OF SEPTIC WOUNDS

By KENNETH GOADBY, M.R.C.S., L.R.C.P.
LOND., D.P.H. CANTAB.,

BACTERIOLOGICAL SPECIALIST ROYAL HERBERT HOSPITAL, WOOLWICH
LECTURER OF BACTERIOLOGY NATIONAL DENTAL HOSPITAL, ETC

(A Report in three Sections to the Medical Research Committee)

(WITH ILLUSTRATIVE PLATE)

SECTION I—SINUSES AND SINUS FORMATION

Scope of Inquiry

AN attempt has been made to study the bacteriological flora of the wounds from the moment of admission to hospital, and subsequently through the various stages of the illness, correlating the bacteriological knowledge with the clinical symptoms, surgical treatment, and sequelae. The condition of the blood was also studied in relation to the degree and variety of sepsis and particular attention given to the benefit or otherwise of the use of bacterial vaccines. As the inquiry progressed certain other problems related to the persistence of unhealed wounds with sinus formation and the appearance of general disturbance with secondary attacks of fever and inflammation often associated with trivial surgical interference with the wound demanded special attention. The inquiry is divided into three main lines of research, necessitating a division of the report into three sections, mutually interdependent—namely, (1) Sinuses and sinus formation, (2) Vaccine therapy and wound infection, (3) General tissue reactions in wound infection.

The following schedule indicates the scheme by which the data of the report were obtained.

1 *Bacterial flora and clinical symptoms of various degrees of injury* which have been classified as far as is possible to do so into four classes (a) Simple flesh wounds (b) Flesh wounds with considerable damage and bruising to the soft parts but without definite bone injury, as determined by radiographic examination (c) Wounds with bone injury, compound comminuted fractures, &c (d) Wounds involving joints with or without fracture of bone, abdominal wounds, skull and spinal wounds.

2 *A critical inquiry into the use of bacterial vaccines as an adjunct to other methods of treatment*—The cases for this part of the investigation were selected in pairs conforming to the four classes noted above. One case was given vaccine treatment and the other retained as a control. As far as possible cases from the same convoys were selected wounded on or about the same date and treated in the same ward under the same medical officer and general surgical procedure. When this was not possible great care was exercised to select cases with similar surgical conditions and subjected to the same treatment. The clinical history of the cases was carefully followed from the records kept in the wards, temperature charts, &c.

3 *Alteration in the blood in cases of wound infection* relating both to the corpuscular elements and the serum. Several points of diagnostic and prognostic importance have been studied and will be subsequently dealt with.

4 *The bacterial flora of sinuses and the bacterial factors in so-called "flares" following secondary operations*. Many of the cases originally examined in the base hospital are transferred to an auxiliary hospital and are readmitted to the base hospital for further surgical treatment or for medical boards. The presence of sinuses and sequestra in many of these cases called for special attention, and several important facts bearing on treatment have come to light and as the observations have extended over a considerable time the cases are representative of the general types of wound infection.

Bacteriological Methods

As the routine methods in use have been the same throughout the whole of my investigations a preliminary epitome of them will be given.

No. 4245

In every case films of the pus were examined microscopically stained by Gram's stain counterstained with dilute carbol fuchsin. In some instances further films were examined with Giemsa's stain and Muir's capsule stain.

Cultural Methods

The material (pus or other discharge) was collected before the wound was dressed by means of a sterile swab on a long stout wire, enabling the depth of the wound to be examined. In the case of closed cavities, sequestra, &c., a swab of the surgeon's wound was obtained before the cavity was entered and subsequently from the depth of the cavity, avoiding the external part of the wound. Portions of bone from sequestra, callus, pieces of muscle, and other tissue were also examined and a portion further submitted to histological examination. The material so obtained was inoculated on to the following media (1) egg broth, (2) glucose formate broth, (3) minced autoclaved meat, (4) autoclaved milk, (5) gelatin. The milk, egg broth, and meat were heated and a layer of liquid paraffin poured on. For the sowings the original material was suspended in broth and inoculated (1) into the egg broth without previous heating, (2) heated to 60° C for 15 minutes and sown in milk, (3) heated to 80° C for 5 minutes and sown in meat, (4) on to the gelatin and glucose formate broth without heating. If plenty of the original material is present in the broth emulsion before sowing, especially blood and bits of tissue, the paraffin method was found to be reliable, and has rarely failed to give a good growth of all the organisms seen in the pus films. The results compared very favourably with those obtained by the anaerobic jar method, and the process is economical with regard to space. Subcultures on to paraffin covered media are not so satisfactory, and further subcultures and plates were treated in the anaerobe jar.

Preparations of the egg broth and glucose formate broth, meat and milk at 24-48 hours were stained by Gram and counterstained with carbol fuchsin, hanging-drop preparations were also examined when indicated. By these means an early general diagnosis is possible in 24-48 hours. The smear preparation can be used for provisional diagnosis. Thus a film showing Gram positive bacilli with no spores and the organisms surrounded by a capsule is evidence of infection with *B. perfringens*. Spore forming Gram positive bacilli with clostridial and subterminal spore formation indicate bacilli of the malignant oedema group, or of *B. Rodella III* (Hibler IX.).

The further diagnosis is completed by examination of the cultures and films &c., of the 48 hours growth thus—

Egg-broth—Cocci (streptococci, staphylococci) *B. proteus*, and *B. malignant oedema* produce a thick flocculent precipitate, when malignant oedema is present there may be black staining. *B. perfringens* alone produces no precipitation of egg broth. Evil putrefactive smell is caused by the malignant oedema group and *B. Hibler* groups not by *B. perfringens*, the latter only causing a butyric smell.

Milk—*B. perfringens* produces a "stormy clot"—i.e., acid with evolution of gas which causes the clot to be broken up, it often adheres in torn fragments to the side of the tube and considerable contraction, at first suggesting peptonisation, occurs, but no subsequent digestion of the clot takes place. Streptococci and staphylococci produce acid and occasionally clotting, no digestion. *B. malignant oedema* does not affect the milk in 24 hours, and in the presence of rapidly growing *perfringens* not at all. Alone and in combination with *B. perfringens* digestion occurs slowly. Hibler IX. (*Rodella III*) has a very slow peptonising effect.

Meat—Streptococci and staphylococci have no marked action. *B. perfringens* group causes a red colouration, peptonisation and gas formation, and a smell of butyric acid but no putrefactive odour. Malignant oedema and *B. Hibler* produce peptonisation, malignant oedema blackening, isolated black patches in a reddish brown matrix are often seen, indicating *B. perfringens* and malignant oedema. Both malignant oedema and *B. Hibler* evolve putrid gases.

Glucose formate broth—Aerobic organisms belonging to the coli and proteus group, staphylococci and streptococci may be observed, gas formation points to the presence of either the coli or the proteus groups, streptococci from the wound grow feebly on this medium. They are more often found on the egg broth growing into long chains and the claws of streptococci met with appear in the main to be facultative anaerobes. *B. perfringens* may grow for a time when many

aerobic organisms are present, it occasionally grows in the glucose formate broth but is easy to detect

Gelatin—Stab cultures on gelatin may show liquefaction in 24 hours. This is usually due to the presence of the proteus group.

For the purpose of diagnosis the following characters were relied upon—

Anaerobic Bacilli Group

(A) *B. malignant edema*—Gram positive, in old cultures three days or more Gram negative, motile spore forming obligatory anaerobic bacilli, spores oval and round. Spore formation very rapid central and subterminal, but always with a small portion of the bacillus beyond the spore in the latter case (Fig 1). Clostridial forms characteristic. Egg-broth thick precipitate often yellow, meat black deposit meat peptonisation with disgusting putrefactive gas. Woolly colonies on plating out, with white opalescent change in egg agar medium, serum and Dorset egg liquefied.

(B) *B. perfringens* group—Large Gram positive, often Gram negative, non motile bacilli, spore formation rarely seen except upon serum and egg medium without broth. Tendency to stain irregularly on using Gram's black dots and bars, the latter may be parallel to the sides of the bacillus stain "Stormy clot" and acid and gas on milk. No liquefaction of serum (Fig 2). Glucose and lactose acid and gas. Colonies smooth, not woolly.

(C) *B. Hibleri* (Rodella III)—Slightly motile or non-motile Gram positive bacilli rapidly becoming Gram-negative. Oval terminal spores general eccentric to the long axis of the organism. The bacilli are often very long and may show double spore formation (Figs 3 and 4). Ordinarily a number of organisms with partially developed spores are seen in culture (Fig 4). In these instances the area of spore formation stains a much deeper colour with Gram's stain than the remainder of the bacillus. Peptonisation of meat with foetid smell, slow peptonisation of milk. Smooth colonies with slightly thickened crenated edge, not woolly.

(D) *B. necrosis*—A long non motile Gram negative slender and often pointed end bacillus growing with considerable difficulty. No spores are formed. Meat undergoes peptonisation, no gas and no clot or acid formed in milk. Diffuse woolly colonies with long tangled thread formation.

Aerobic Group

(A) *Coli* group—Lactose fermenting organisms. Gram-negative non sporing motile, non liquefying. The various members of this group are under examination and will be recorded in a later communication.

(B) *Proteus* group—Non lactose fermenting organisms, motile Gram negative non sporing, gelatin rapidly liquefied, facultative anaerobic. Milk digested without acid formation.

(C) *Cocci* group—*staphylococci streptococci*

B. procyaneus was isolated on many occasions often appearing and disappearing in the wounds in a manner suggesting secondary or aerial infection although no other cases with blue pus were present in the ward. There was no apparent co-relation between the clinical symptoms and the presence of this organism in any but a very limited number of cases. The routine examination of the aerobic group was

mixtures the dilution method was followed surface smears being used only for studying the individual colonies of pure cultures. Various anaerobic cocci especially an anaerobic streptococcus and an irregular coccus probably diplococcus magnus of Tissier were observed often mixed with the malignant edema colonies (See Fig 4).

General Explanation of Tables I and II

In Tables I and II I have collected some of the more important facts relating to 77 cases of wound infection and sinus infection. Of the cases of Table I 14 appear in Table II, but only in 2 are the dates of bacteriological examination the same.

Table I is a record of the latest bacteriological examination that was made in the given case, while Table II gives the earliest examination made after the time of wounding. Various intermediate examinations were made in many of the cases, but these details are omitted from the tables for the sake of clearness. The tables show the bacterial flora met with in recently inflicted wounds and the organisms met with at long periods afterward. In Table I the bacteria found in 10 different closed cavity cases are also given. In these instances the external wound was entirely healed over, and the operation was undertaken for some surgical reason other than the presence of a septic focus, in fact there were no evidences of any septic trouble. In none of the cases was operation followed by reaction, febrile or local. These cases are a curious control to the "sinus cases," many of which certainly more than 1 in 10 showed a febrile reaction with local symptoms of inflammation and it may well be that tissues still suppurating with an external open sinus are barely holding their own against the various bacterial agencies at work, whereas in the closed cavities the infecting organisms though not destroyed, are shut off from causing trouble by a wall of protective tissue.

In addition to the *B. malignant edema* and *B. perfringens* another anaerobic spore forming bacillus with end spores closely resembling the *B. tetani* was isolated from 41 cases. This organism originally described by Rodella¹ and latterly carefully studied and described by Hibler as *Brellus IX* has received little attention by recent observers as an organism common in the wounds. In none of the 77 wound cases was *B. tetani* isolated although organisms morphologically resembling it were common. The original egg broth cultivations containing these end spore organisms were kept three or four weeks and then inoculated into animals in all suspected cases and in no instance did the animal develop symptoms of tetanus. In 2 cases only of clinical tetanus have characteristic symptoms followed the injection of cultures in guinea pigs, neither of these cases is included in Tables I and II. Dudgeon² claims to have found *B. tetani* in 11 out of 21 cases examined and makes a number of deductions from the fact. Fleming states that he found *B. tetani* in 22 cases out of 127 examined in the first seven days following injury and 5 out of 56 examined between the eighth and twentieth day. Neither Dudgeon nor Fleming states the grounds of their diagnosis of *B. tetani*, they make no mention of animal experiments which is regrettable. On the other hand Dean and Moore³ observed the presence of *B. tetani* in 4 cases out of 16 examined (the day of disease is not mentioned) in all 2 cases the inoculation of animals produced typical symptoms.

wound, when all clinical symptoms of fever and other constitutional disturbance have disappeared.

Bacteriology of Sinus and Closed Cavity Cases

Chronic sinuses, often determining general constitutional disturbance when operated upon, are very common, and the problem of dealing with them is urgent. Owing to the splintering of bone and the amount of bruising suffered by the soft parts, the initial stage of healing in many wounds is frequently greatly delayed, the purely mechanical damage to the tissues promoting the sequestration of micro-organisms in fragments of bone and developing granulation tissue. Not only are nooks and crannies present in the interior of severe wounds, but the granulation tissue thrown out by the injured surface is indolent, low in resistance, and while invading organisms become phagocytised by the wandering cells by no means all are destroyed. In a recent publication Peyton Rous and F. S. Jones¹¹ call attention to the protective action of living cells upon bacteria. Experiments with a specific hæmolytic serum and the appropriate red cells showed that the red cells when englobed by phagocytes were protected from the lytic action of the specific serum, although any cells remaining unphagocytised were quickly dissolved. Using trypan blue as an indicator of the death of the cell, Rous and Jones were able to show that the cells which had taken up the red corpuscles were still living and exhibited considerable resistance to various destructive agents, the protection against the action of the homologous hæmolytic serum appeared to be a characteristic of the living cell. Testing this hypothesis with typhoid bacilli it was found that a concentration of N/150 potassium cyanide killed typhoid bacilli in a suspension of guinea pigs' corpuscles without destroying the life of the corpuscles themselves, with the result that the bacilli contained in the cells were protected and grew when the emulsion was plated out, no growth occurring in the controls.

There is little doubt that continued reinfection of the walls of a sinus takes place through phagocytic action, and the difficulty of eliminating bacteria implanted in the granulating walls, so well known clinically, is explained by Rous and Jones's valuable observations. Moreover, the use of hypertonic salt solution, which invariably produces flabby granulation tissue when continued for extended periods would seem to aid the sequestration of phagocytosed organisms. Hyperchlorites exert a solvent action on dead and partially dead tissue, and it is possible some of their activity is due to this action as well as their bactericidal properties. As a general rule during my investigation of sinus and septic wounds material obtained within half an hour after dressing with either iodine peroxide or saline has given substantial bacterial growth but in very few instances have I obtained cultures within half an hour of hyperchlorite dressings.

From the clinical point of view the sinus case causes anxiety. Firstly it goes on for a very long time and although the patient may not be ill yet is entirely incapacitated from duty, secondly attempts to close the sinus surgically may cause a "flare" or only result in further chronic suppuration, even a healed wound constantly breaks down again without any adequate surgical cause.

In September 1915 Colonel Bond¹² called attention to the recrudescence of sepsis or local reinfection, and cites several cases where severe local inflammation followed trivial surgical procedure such as passive movement to a joint in the vicinity of an old wound. Colonel Bond says: "Is the capacity of organisms to remain alive and virulent the result of the formation of fibrous tissue," &c. and further: "Is the time interval of essential importance?"

Mr Jocelyn Swan and myself¹³ noted a series of cases of 'closed cavities' in which a careful bacteriological examination was made. Cultures were obtained at operation from the cavities containing foreign bodies after complete healing of the entrance wound. Four of these closed cavity cases are included in Table I (Nos 34, 39, 40, 41). At the time that paper was published the investigation on sinus infection was proceeding. The research is still in progress but sufficient details have been accumulated to warrant a preliminary communication. I have, therefore collected into tabular form (Table I) certain of the more important facts relating to the bacteriology of sinus cases and closed cavity cases showing the day after the infliction of the injury upon which the bacteriological examination

was made the clinical variety of the injury, the organisms demonstrated, and some of the essential clinical notes relating to the cases. The organisms isolated are scheduled according to the grouping already given, and the letters and figures in the second column refer to the cases as classed under the four headings indicated above. The earlier bacteriology of the wound is omitted from Table I, but the details of 11 cases are given in Table III.

In many of these sinus cases bone injury had been a prominent feature of the original wound, and the cultivations in which anaerobes were obtained were made from the necrotic or exposed bone at the bottom of the sinus at operation. Cultivations had been made from the suppurating sinus from time to time before the removal of the sequestrum was undertaken, and these uniformly failed to show anaerobes. The organisms encountered in the soft parts of the sinus were mainly streptococci, staphylococci, and members of the proteus and coli groups. In only one instance (No 17) did anaerobic infection follow operation, extensive incisions were made, including transverse muscle incision, and the case recovered. B malignant oedema was present in the pus films in large numbers.

Sinus Cases which were Followed by 'Flares' after Subsequent Operation

In 13 cases (Nos 1, 2, 6, 7, 10, 11, 12, 16, 17, 21, 25, 28, and 31) temperature reaction, in certain instances very severe followed the operation. Two typical cases may be quoted—

CASE 12 (72b).—Shrapnel wound of left shoulder with moderate bone injury. On the 80th day after injury a sinus leading to the damaged shoulder being present a small piece of bone was removed with sinus forceps. An acute attack of erysipelas came on within 48 hours associated with a severe attack of fever, the blush around the wound, arm and chest, remained for eight days. On the 109th day another small bone fragment was removed and a similar attack took place (See Chart 1). The bacteriological examination gave an almost pure growth of streptococci from the sinus, malignant oedema and B perfringens from the extreme depths of the wound. There were no symptoms of gas gangrene or tissue emphysema. A dose of polyvalent streptococcal vaccine (5 x 10⁶) was administered immediately after an examination of the pus films and three days later 5 x 10⁶ of autogenous sensitised streptococcal vaccine was injected. The temperature (see chart) rapidly fell, two subsequent doses of vaccine were administered. On the 122nd day some further pieces of bone were removed with no rise of temperature or other reaction. In this case there was good drainage of the wound, and the bone fragments removed were out of all proportion to the "flare" which followed. The case made a speedy recovery.

CASE 6 (68d).—The second case was not a gunshot wound, but a fracture due to a motor accident. The femur was put up on the second day the tibia plated on the 12th day, and the stitches removed on the 22nd day. On the 29th day massage and movement of the knee were commenced, followed almost immediately by acute pain, and on the 32nd day an incision was necessary. Streptococci were present in large numbers. On the 43rd day another incision was made. On the 47th day the plate from the tibia was removed, which was followed by a very severe reaction with pus in the knee joint. The autogenous vaccine prepared was given inadvertently on three occasions at intervals of 24 hours then discontinued (Chart 2). The febrile period lasted till the 81st day. Subsequent exacerbation of fever with local redness and increased pus development took place on four subsequent occasions. A reinvestigation of the bacteriology as before, a new autogenous and sensitised vaccine was prepared and administered at appropriate intervals. No further rise of temperature occurred, and three subsequent operations including curetting the sinuses related to the knee joint were performed without any temperature reaction or local tissue inflammation although at the last operation no further "flares" have taken place although two more vaccine treatments were performed, and under the influence of the has disappeared, and normal tissue is developing.

CASE 23 (12c) is an example of severe sepsis with compound comminuted fracture which finally recovered without sinus formation.

The tibia of both legs were plated and vaccine treatment somewhat late (22nd day). A large secondary abscess was incised on the 49th day, the temperature fell to normal on the 75th day, one other abscess having been opened. From

CHART 1

this time to his transfer to a convalescent home on the 146th day no further rise of temperature took place and no sinus was present (Chart 3)

CASE 10 (35c) is of special interest as it was a control case to 52c (Table II)

The two men were readmitted on the same date (177th day of disease), the one with an entirely healed wound and no tenderness and complete, but irregular, union and no sequestrum. The control case with a similar original wound and bacteriological picture had two unhealed sinuses leading to bone, several operations and attempts to close the sinuses had failed. Bacteriological examination showed the presence of *B. perforans*, *B. proteus* and streptococci; an autogenous vaccine was prepared and administered. The case still under treatment has healed up twice but has broken down again; no operation has been performed on the sinuses since vaccine therapy was commenced.

cines before the next operation was performed, none of these cases flared. In no single instance therefore, was any subsequent operation followed by a flare when previous appropriate vaccine treatment preceded the operative

RT 2

Disease Comp Comm Ract Femur

measures. All these sinus cases had suffered from severe tissue laceration when wounded no doubt predisposing the local persistence of the organisms concerned in the flare. The figures given are an example of the great advantage of vaccine immunisation as a preliminary to operative interference with the chronic sinus.

There is also evidence that vaccine therapy is of value in the earlier stages of these wounds. In Table II I have set out certain particulars relating to the vaccine treatment of 47 severe and septic wounds in their earlier stages. Although the general discussion of my observations on vaccine therapy

СПАИТ 3

Admission of the Irrigation to the Provisions to Operation

In 22 cases in Table 1 vaccine inoculation had been given at intervals for at least two years previous to subsequent operation. In no instance was the operation at ended because of a "flare" (No 1 4 5 6 7 8 9 10 12 14 18 19 20 21 23 25 26 27 28 33 35 and 43). In 8 (Nos 16 7 10 12 21 25 and 29) of this series a "flare" had followed a previous "flare" operation but after the administration of the appropriate vaccine no disturbance followed the later operations performed. The cases of cerebral abscess had no vaccine treatment and 11 of the 20 operated Case 20 "flared" in the post-operative period with an abscess cavity containing "pus" but in 10 in 11 spinal cases no relative vaccine treatment had succeeded to relieve

is reserved for the second section of the report, Table II has been introduced as some of the facts, especially the bacteriological findings, are of interest in relation to the later bacteriology of the sinus cases. Fourteen of the cases are ones that also appear in Table I, these cases are collected in Table III, and the first bacteriological examination made

v Vaccine case o No vaccine.

subsequent to wounding compared with the final examination of the sinus or sequestrum. Three of the 14 cases are omitted from Table III, as the particulars of the bacteriology given in Tables I. and II. refer to an examination on or about the same date.

There is no indication in the results that the use of the vaccine in the early stages of the wounds had reduced the anaerobic flora of the sequestrum or sinus. In the cases in which *B. malignant* oedema persisted one was an injury affecting the sacral canal (2d). Two were cases of sequestrum formation, no anaerobes were present in the sinus pus. One case was a simple sinus without bone injury, and only received two injections of vaccine before he was transferred to another hospital and the inoculations suspended. In seven of the eight cases in which *B. perfringens* and *B. Hibler* were recovered from the sinus at the final examination there was bone involvement, the cultures were obtained either from the sequestra or bone scrapings from the depths of the sinus. Six were vaccine and two non vaccine cases.

The aerobic organisms showed no striking diminution in incidence. On the other hand it would be unwise to deduce, therefore, that vaccine therapy had effected no beneficial result, in fact, it is doubtful if the presence or absence of a given organism determined culturally in a sinus even where a specific antigen has been administered, is any test whatever of the benefit or otherwise of vaccine therapy. Many factors are concerned in the growth or persistence of organisms in a sinus. Rous and Jones's work points to one problem that deserves consideration, the physical impermeability of fibrous tissue effectually preventing the permeation of the bacterial infected areas by the blood antibodies is a second, and the presence of a sequestrum is a third. That vaccine therapy has little direct action in affecting the flora of a sinus and none whatever upon formed sequestra may be concluded from the facts collected in the foregoing tables.

Effects of Vaccine Therapy

Theoretically the production of antibodies by the injection of the appropriate vaccine depends upon the reactivity of the tissue into which the antigen is injected. A man therefore, who is in normal vigorous health at the moment of wounding, and until the development of toxin and bacterial products in the damaged tissue has lowered his initial high resistance to bacterial invasion, may be regarded as a peculiarly favourable case in which to raise the specific resistance against specific forms of bacterial invasion. Theoretically the injection of appropriate antigen if undertaken early, should produce an increased resistance—

1. To general constitutional disturbance immediately following subsequent surgical manipulation of the wounded and largely circumscribed by the natural protective action of the adjacent tissues.

2. To the spread of the bacterial invasion in the immediate region of the damaged tissue, the damaged tissue consisting not only of the actual wounded tissues but the greater or less area which has suffered molecular disturbance without solution of continuity in direct proportion to the velocity of the projectile.

The evidence adduced in Table I. of the decreased liability to "flares" in cases in which vaccine therapy has been used systematically and the prevention of "flares" in cases which have already shown a "flare" following secondary operation gives good reason to conclude that the first of the above theoretical possibilities can be realised when vaccine therapy as an adjunct to surgical treatment is practically employed, and that the theoretical considerations suggesting the use of antigen inoculations coincide with clinical observation in properly controlled cases.

The second of the two theoretical premises stated above receives considerable support from the cases in Table II. These cases, which were selected in pairs generally from one convoy showed similar bacteriological pictures and suffered from directly comparable injury were for the most part treated under identical conditions as to surgical method, dressing, antiseptics, &c. The clinical history was obtained from the notes kept in the wards, and it was not until a table was compiled that secondary hæmorrhage was found absent in the inoculated cases and present in the controls.

It will be seen in Table II. that in the 24 cases treated with vaccines no case of secondary hæmorrhage took place while in the 23 control cases no less than 8 suffered from septic secondary hæmorrhage. In two instances the hæmorrhage recurred 3 days and 15 days after the first attack. Of the 8 vaccine cases 6 were dressed with hydrogen peroxide, hypertonic saline, or saline and iodine, 2 were dressed with eusol. The 8 control cases were dressed in a similar manner, 2 only with eusol. Other treatment was exactly similar, and the injuries were strictly comparable.

Bacterial Flora of Wounds

The cases of Table II. were for the most part wounded in the earlier part of 1915, at Neuve Chapelle some in the battle of Loos. Recently the cases of secondary hæmorrhage have been less frequent and the bacterial flora of the wounds investigated somewhat less complicated. There is a general agreement in my series of cases between the time of year (and therefore the earth temperature) and the severity of the wound infection. This point will be dealt with in a later section. A glance at Table II. shows the very heavy infection found in the majority of wounds examined and demonstrates that the bacterial content of the wound alone is by no means the only factor in the determination of severe local or even generalised infection. On the other hand, the cases of acute gas gangrene which have come under my own immediate observation in the acute stage have shown a preponderance of sporing bacilli with mid or sub terminal spores and many clostridial forms in the tissue smears (*B. malignant* oedema) or large Gram positive non sporing bacilli (*B. perfringens*).

In the sinus cases and the wounds without clinical symptoms of gas gangrene the Gram positive anaerobes were not in the majority and sporing forms are not very common. Gram negative bacilli were frequently seen, some of them probably degenerate forms of the *B. perfringens* and malignant oedema others belong to the proteus and coli group. Streptococci are not often found in chain form except in the cultures, in the tissue smears they mainly appear as diplococci.

Fig. 6 is reproduced from a photograph of a tissue preparation from a case of acute gas gangrene. The bacilli are seen lying in the muscle bundles themselves, and a considerable area of semi digested tissue surrounds the organisms. The appearance certainly suggests tissue digestion and further supports the view already enunciated that the anaerobic bacteria in sinus cases are of more importance as tissue digesters than tissue invaders.

Conclusions of Section I

To recapitulate briefly the conclusions of the first section of my report I find in septic wounds and in sequestra forming as the result of such wounds—

(A) A preponderance of certain classes of anaerobic bacteria—namely, organisms referable to the groups (1)

B malignant œdema (Koch), (2) B perfringens (Veillon), and (3) B Hibler

(B) A small incidence of B tetani, at present only in cases of clinical tetanus

(C) That wounded tissues especially sequestra, contain anaerobic bacteria months after the original injury, even when the external wound has healed

(D) That infection of the wounded and partially healed tissues with anaerobic bacilli predisposes to sinus formation

(E) That persistent infection of wounded tissues is the chief if not the essential, factor of the "flares" occurring after operations upon sinuses

(F) That the use of appropriate vaccine therapy properly controlled is an important and urgent concomitant of surgical treatment in (a) the prevention of "flares" after secondary operations, (b) the prevention of sinus formation, and (c) the prevention of secondary hæmorrhage

(G) That the biological (digestive) activity of anaerobic bacilli is more important than the specific infectivity

As a result of my investigations into sinus cases generally I would suggest the following routine treatment for chronic sinuses resulting from gunshot and other projectile wounds. The presence of bone involvement or sequestrum should be determined by radiography. If a sequestrum be present anaerobic organisms are almost certainly present. A bacteriological examination may or may not determine this point before operation, but the case should be treated as if anaerobes were present. An autogenous vaccine and preferably sensitised vaccine should be made from the organisms in the sinus, streptococci and the coli or proteus group when present must be included. If time is an object a stock polyvalent vaccine may be used, having regard to the bacteriological findings. Should the preliminary inoculation give rise to constitutional disturbance a "flare" would presumably have followed an operation undertaken without previous immunisation. Such cases should not be operated upon until efficient immunisation (three weeks at least) has been carried out. If no constitutional symptoms follow an autogenous (not stock) vaccine operative treatment may be proceeded with, as only the minority of such cases "flare". The doses of vaccine given should commence with 5×10^6 of streptococci 10×10^6 of B proteus, and 5×10^6 of B coli. The inoculation should be repeated at 3-5 day intervals, increasing the dosage with reference to the clinical symptoms. Three days subsequent to the fourth dose the sinus should be surgically dealt with. Possibly excision of the sinus walls would give better results than scraping with a sharp spoon, in fact the bacteriological and physiological considerations suggest this as the procedure least likely to contribute to further invasion.

From the results recorded in this report it would appear that the anaerobic bacteria even if present in the sinus may be disregarded providing proper precautions are taken (1) to immunise the patient before operation, and (2) to provide an efficiently drained wound.

The biological activities of the anaerobes do not apparently come into operation unless aerobic organisms especially the proteus group provide a suitable nidus or if tissue destruction (scraping) cause already damaged tissue to die off. After operation hypochlorites (Dakin's solution) may be used with advantage and the wound treated as an anaerobe infected one.

All chronic sinuses which alternately heal and break down should be treated by vaccine therapy before subsequent surgical procedure is adopted.

DIGITALIS IN AORTIC INCOMPETENCE

By SEYMOUR TAYLOR, M.D. ABERD., F.R.C.P. LOND. &c.,
CONSULTING PHYSICIAN TO THE WEST LONDON HOSPITAL, ETC.

THIS is an old subject, but it is by no means threadbare. I have written and spoken on it in previous years, and have made contributions to our literature bearing on this disease as other observers have done. But without wishing to appear didactic, I think it well to add my further experience to strengthen the views which I hold.

As one lives longer and sees more cases, and also registers the results of treatment, or the failures and successes of prognosis, one becomes more impressed with the value of clinical experience as against the theories of the laboratory or the seductive whisperings of a physiological instrument. So far as prognosis is concerned, there are some fixed opinions on the subject of valvular affections of the heart. And no opinion, so far as my experience goes, is so firmly established as is the seriousness of aortic regurgitation. Even in youth it is a lesion of the gravest character. But in a man or a woman upwards of 40 years of age even should the causal disease have been only recently acquired the outlook is always serious, though as I shall show, some sufferers may survive to good old age. Perhaps I may put the whole question of prognosis in a single sentence by saying that in life assurance any applicant having aortic insufficiency should be "loaded" 100 per cent. If he be young but if he be over 45 years of age his proposal should be rejected.

But not only is the prognosis always grave not only must we admit that the sufferer has in the majority of instances a shortened span of life, but that all who have had opportunities of observing these cases and of recording their longevity must also be convinced that the immediate prognosis is one which requires cautious utterance. The various eddies, cross currents, and commotions in the stream of life are complex and beyond our control. Hence a violent emotion, an exciting episode, or a sudden muscular effort may bring disaster to the sufferer from aortic incompetence, notwithstanding that to all outward appearances he may hitherto have been in the enjoyment of a fair amount of health and with little or no distress. The patients who do fail under these adverse circumstances die suddenly, suffering little or no pain themselves, but on the other hand many survive beyond middle age and lead useful if not laborious lives.

I have now for many years past been observing and recording the life histories of patients who have suffered from aortic regurgitation and who still survive or who have survived to a recent date. I have so far as I could obtain information thereof made notes of their ages when death overtook them, and I have in many instances ascertained the form of death whether sudden or lingering, and also have I specially inquired whether digitalis had been administered during the last or fatal illness, or whether death occurred without warning and without any special cardiac treatment. And here I may observe that a careful inquiry will reveal the fact that many sufferers from aortic incompetence are unaware of the fact that they do not seek medical advice for any symptoms referable to heart disease and further that many of them perform arduous work entailing prolonged muscular exertion with distress or discomfort. The experience of the French military doctors as recorded in THE LANCET of Jan. 30th 1915 proves all this. The soldiers who had been on active service and were sent to hospital from the front were

aortic incompetence, and this being such a serious affection our whole attention must be given to it, any other valve lesion being of minor interest and importance.

I have for many years tried to show that aortic incompetence by itself is not only a most serious lesion, but also that its gravity and its discomfort are enhanced if the mitral valve is holding and competent. This may appear to be a paradoxical statement. But I have abundant evidence, derived from observing numerous cases, to convince me that mitral regurgitation is really a boon to sufferers from aortic regurgitation. Some argue that two lesions cannot be more advantageous than one. I am not so sure of this. We see compensatory hypertrophy, which is obviously an abnormality, in certain muscles when the spinal column is distorted. It cannot be said that a hypertrophied left ventricle is a healthy or normal condition yet it obtains in chronic kidney disease with changes in the arterial system. I often wonder how a long distance runner would complete his course without the so-called 'physiological' action or overflow of his tricuspid valve, by which his labouring right ventricle is relieved. This phenomenon is one of the first things which we learn in our text-books.

Transferring our attention to the left side of the heart we can then recognise how a bicuspid valve (mitral) may, by its leakage, allow a similar relief, a lessening of centrifugal tension, notwithstanding that it is pathological. Even allowing that this is conjectural, I have records of many cases, in early middle age who have led and who still lead, lives of comparative comfort, they having the double lesion, whilst, on the contrary others having only an aortic incompetence, suffer dyspnoea, faintings, and other discomforts, and are incapable of any beyond the slightest exertion. If there is one fact which has impressed itself on my mind when studying cardiac affections it is the comfort which an imperfect mitral valve bestows on a patient who has an incompetent aortic valve also. Let me admit, however, that I have no scientific proofs of these statements. I can only record clinical experience. Here are two cases in brief detail.

CASE 1.—An insurance clerk now aged 27 had chorea at the age of 11. He was known to have a "weak heart." His father brought him to me when he was 18, with a view to ascertain what occupation he was then best fitted for from a physical point of view. I found that he had unmistakable signs not only of aortic regurgitant disease, but of mitral regurgitation in addition. He has been in his present employment now for upwards of nine years, he has suffered from no dyspnoea, angina or oedema, and he recently told me that he could run upstairs without discomfort, and that he often had to race uphill to catch his morning train to London. I can see no reason why this young man, knowing his infirmity and taking proper precautions (I have scolded him for disobeying my orders about running), should not live in comparative health and comfort to at least middle age and possibly longer, though his life must always be regarded as a precarious one.

CASE 2.—The patient a man aged 39 was seen by me 17 years ago. He had typical signs of aortic regurgitation due to an attack of acute rheumatism when he was 20. The mitral valve then was apparently intact. I saw him again last year after he had had a second attack of rheumatic fever. I then found that he had a systolic murmur, loudest at the apex, distinctly heard at the angle of the left scapula and attended by accentuation and reduplication of the second sound over the pulmonary artery. The signs of his old aortic incompetence were also quite evident. He came to see me more with the view to ascertain my opinion as to whether he could be employed as a builder's foreman, and singularly enough he volunteered the statement that since his second attack of rheumatism he had had less dyspnoea, and was more able to perform active duties than during the period between his first and his second attacks.

By some physicians my conclusions may be classified as speculative only. But as Darwin has shown no good or original observation can be made without some speculation. The brilliant discoverers of the origin of malarial fever, of plague, and of other devastating diseases only made speculative and conjectural observations at first. Others again, have effected cures by means of serum therapy by the administration of drugs and of glandular extracts, but the scientific proof of how the various diseases are thereby cured has not yet been divulged. Similarly one may object to the statements of clinical events (I call them events rather than facts for the present) as not yet capable of scientific proof. But I contend that if there is an overwhelming amount of good evidence in favour of one or against another certain

line of treatment, then we must accept facts and wait for their elucidation by experimental proof till some future period.

The efficacy of a drug in the majority of instances has been ascertained by clinical experience rather than by laboratory research. The effect noted by a certain drug on the heart and pulse of a dog is not conclusive that a similar effect will be produced on a human's circulation by the same drug. Some animals consume what are to us poisonous plants with impunity, and I have little doubt that the converse applies. Therefore, I contend that one's experience should guide us in giving advice in the treatment of disease. Experience, after all, is a firm bed-rock on which to base statements dogmatic or didactic though they be. The mason builds from below, he knows really nothing of the laws of gravity, yet he has the intuition that if he attempts to build in any other manner disaster awaits him. When the keystone is in position he may then survey his work with satisfaction, and may with greater ease and understanding listen to the explanation of the laws of thrust, expansion, and other varying forms of what is really gravity. If the opinions of some others differ from mine I must accept them but I can accept no surmise, I must have quoted facts derived from records of cases which have been carefully observed.

To my younger confrères, therefore I would say "Keep notes of your cases of aortic insufficiency, record their longevity, their modes of death, whether sudden or lingering, and compare a series of cases treated by digitalis with another series of cases in which the drug has had no place in the defence." Obviously I am only referring to those cases of aortic regurgitation which, in the opinion of the medical attendant, require medication—cases which show signs of ventricular dilatation and cases in which attacks of dyspnoea come and go, and even those cases in which the medical attendant may, and often does, say with perfect faith, "Your heart requires a tonic from time to time, therefore keep this prescription in your pocket and occasionally take the remedy." I wish to caution such doctors. Sudden death in these cases is by no means uncommon. I have received not a few letters from younger practitioners in which they have related cases of sudden death, although no sign of such an impending event was manifest. But their consolation was "My teacher always advocated digitalis in these cases", or "Dr So-and-So, under whom I studied, was in the habit of prescribing the drug." And this places me in a difficulty, for I know that eminent men have been quoted. But I will make one qualification—a qualification which I have made before—to my objection to the use of digitalis in aortic regurgitation. If in addition to aortic insufficiency the patient has also mitral regurgitation, then digitalis is a useful remedy.

Now the chief object of this communication is to put on record some addition to the number of cases having aortic regurgitant disease who have survived to old age and to whom digitalis has never been given since I have had them under observation, now some 10 to 15 years. I prefer to leave out any further record of cases which after a course of treatment by digitalis have died suddenly as such a record might occasion some distress. I have had it said to me that better authorities than I have advocated the use of this drug in case of threatened cardiac failure, even when the cause thereof was simple aortic regurgitation, that even in those cases which after a regulated course of the remedy, do die suddenly, it was only a natural event one to be almost anticipated and not due to digitalis. All I can do in reply, is to mention that I have received letters from doctors, and have records of cases, confirming my experience, and what to my mind is stronger evidence is obtained from the experience of cases which survive, or have survived, to old age, without their having had a single dose of digitalis. It will therefore be well if I record three more such examples.

CASE 3.—A wealthy gentleman, with every worldly comfort, was first seen by me when he was 69 years. He had every sign of aortic regurgitation—diastolic basic murmur, shaking carotids capillary pulsation, Corrigan's pulse, &c., but his mitral valve was intact. During the whole of the period, his doctor, he never had him under observation with although he had, from time to time, attacks of dyspnoea, and these were successfully encountered by small doses of trinitrin (gr 1/200) and a very diminished dietary, usually about a third of his daily food with one day's fasting in

each week. He survived to the age of 83 and died gradually as though worn out.

CASE 4.—The patient a twin (female), aged 79, was first seen by me 15 years ago. She had, and has now, all the cardinal signs of aortic incompetence but with no evidence of mitral regurgitation. The physical signs are also accompanied by characteristic symptoms, such as periodic attacks of breathlessness, palpitation, with insomnia or nightmare. I advised treatment similar to that which is outlined in the preceding case. She still survives, and is in her eightieth year.

CASE 5.—The patient a female, was first seen by me in 1901 suffering from dyspnoea, accompanied by signs of aortic regurgitation, with crackles at the base of each lung and a tendency to anasarca. I had a suspicion, from the existence of certain well known physical signs, that her mitral valve was not holding completely, this suspicion being strengthened by the signs of back pressure. Still, acting on my advice and wishes digitalis, although suggested, was not given. I hear that she died last year in her eighty-seventh year.

Here are three remarkable cases, all octogenarians, who suffered from grave valvular affection, for which probably many practitioners would have from time to time prescribed digitalis, since it will be noted that these cases were not without symptoms of distress, that they were not examples of cases which we frequently see in whom, though the aortic lesion is well marked by physical signs, there were no urgent symptoms. All three consulted me on account of serious indications of distress, which returned from time to time and which called for relief.

These cases, if they show nothing else, illustrate how many people, notwithstanding serious cardiac ailments, may live to good old age by careful treatment and management.

Seymour street W.

ABDOMINAL PREGNANCY, PROBABLY PRIMARY¹

By FREDERICK J. MCCANN, M.D. EDIN., F.R.C.S. ENG.

SURGEON TO THE SAMARITAN FREE HOSPITAL FOR WOMEN,
MARLBOROUGH ROAD, LONDON, W. LECTURER ON
GYNECOLOGY, MEDICAL GRADUATES' COLLEGE
AND POLYCLINIC, ETC.

THE recent researches on the embedding of the human ovum and the definite proof of the existence of ovarian pregnancy established by quite a number of recorded examples have been the means of altering the attitude which has hitherto been adopted towards the possibility of primary abdominal pregnancy. It is now affirmed that the ovum will embed itself in any patch of connective tissue capable of supplying its nutritional demands. That a pregnancy is primarily abdominal is difficult to prove but it is also difficult in certain examples to disprove, for in the light of modern knowledge we can no longer cling to the old statement that "all cases are primarily tubal." If further a detached ovum and therefore a damaged ovum can become implanted and grow on the peritoneal surface, why not a fresh ovum? Now the situation in which this implantation would be most likely to occur is the upper part of the posterior surface of the uterus. An entirely erroneous impression of the position of the appendages is apt to be

an ovary, the seat of a cystoma.² It is therefore not difficult to imagine that it may become implanted in the posterior surface of the uterus.

As a contribution towards the study of this subject let me record the following example. Dr M. H. Huston of Harrow has very kindly furnished me with some facts concerning the patient's previous history, which I give in his own words—

She was aged 35 years and had had three confinements all, as I understand, normal and of short duration the last two years ago. Her menstruation ceased at the end of July 1915. In August and September, 1915 she had an attack of meningitis, probably cerebro spinal, although the meningococcus was not found. I was first called to see her on Friday, April 28th, 1916, and was informed that the 'waters' had come away the previous evening while the patient was at tea. There had been very slight labour pains but these had passed away, and from the description it was doubtful whether they were labour pains or not. During the night the patient had been sick several times. The bowels had acted well with enemata. She complained of pain in the epigastrium, but no labour pains. On examination she was found to be in fairly good general condition colour good pulse 96 abdomen apparently that of a woman at full term. The child could not be definitely felt by abdominal examination, although there was a hard mass in the left side which suggested the head. No movements of a foetus could be felt although she stated that she felt movements distinctly up till the preceding day. On vaginal examination the os was only enough dilated to admit the tip of one finger. No presenting part could be felt and there was no external hemorrhage.

On Saturday and Sunday the patient's condition remained much the same, her chief complaint being epigastric pain, vomiting, and sleeplessness. On the Sunday morning about two teaspoonfuls of blood had been passed per vaginam. No decidua had been expelled. On Monday, May 1st I was summoned to see her by Dr Huston as her condition had become worse. She was a small, pallid spare woman and was sitting up on a chair with her feet resting on the edge of her bed. She complained of pain in the epigastrium and informed me that she had been unable to retain any food. A monthly nurse was in attendance and all preparations had been made for her expected confinement. She was moved on to her bed with some difficulty because any attempt at movement seemed to cause considerable abdominal pains and distress. The abdomen was much distended and there was considerable venous engorgement visible in the abdominal walls. The abdomen was extremely tender on palpation especially on the left side over the position of the fetal head and at other points where the foetus was palpable. It was however, difficult to make a detailed examination of the abdomen because of the extreme tenderness as well as the intestinal distension. The latter was so marked that what I took to be the transverse colon was visible and palpable lying across the upper part of the abdomen. The outline of the uterus could not be defined as the patient at once resented any attempted pressure. The breasts were somewhat atrophied and in appearance were not suggestive of pregnancy, and no fluid could be expressed from either nipple. On vaginal examination well marked venous distension and blue discoloration were noted. The cervix was much softened and drawn upwards and the os uteri at the size of a five shilling piece readily admitted the finger. No presenting part could be felt on vaginal examination. Bimanual examination was unsatisfactory for the reason already given. The patient had an inguinal hernia on the right side and was wearing a truss. When the truss was removed and the hernia examined there was considerable local tenderness and the hernia could not be completely

made a further abdominal examination but was still unable to define the outline of the uterus owing to the tenderness and intestinal distension. The tenderness was still most marked when pressure was made on any part of the foetus. I again advised a policy of delay, and although it occurred to my mind that a rupture of the uterus was a possibility the history and the absence of signs of internal hemorrhage made me decide against it.

Four days later I was summoned by Dr. Lambert, who informed me that the woman had not improved, and that he wished me to see her again. When I saw her she looked pinched and anxious, her pulse was 150, and she informed me that she could not sleep. I again examined the abdomen and succeeded for the first time in palpating the uterus, as both the abdominal tenderness and the intestinal distension had markedly diminished. It was possible to palpate the bones of the foetal head, which imparted a curious crackling sensation to the examining fingers. Bimanually the uterus was pushed somewhat to the right side and corresponded to the size of a five months' pregnancy and as the foetus was obviously extra uterine I decided to open the abdomen without further delay. For two days an offensive purulent discharge had issued from the vagina and the general condition of the patient suggested the presence of a severe toxæmia.

Operation May 11th 1916.—A free median incision was made and as soon as the peritoneum at the upper part of the incision was opened a small quantity of black blood clot presented. On enlarging the incision the umbilical cord of a dark slate colour bulged into the wound. The hand was introduced and a rapid exploration made. The foetus was grasped by the legs and withdrawn without difficulty. It was a female, apparently of full development and the skin of the chest was beginning to peel. The uterus was at once brought up into the wound and was found to be enlarged to about the size of a five months' pregnancy with a well-developed placenta, to which the umbilical cord was attached firmly inserted in its posterior surface slightly to the right side. As the broad ligaments on either side were free the uterus and placenta were brought into view without difficulty. A strong odour of ammonia was perceptible during the operation suggestive of the presence of urine in the peritoneal cavity although the amount of intraperitoneal fluid was inconsiderable. The intestines were carefully packed off with sponges and a rapid supravaginal hysterectomy performed, leaving the appendages *in situ*. The placental attachment seemed to fade away gradually on the lower part of the uterus, leaving the floor of Douglas's pouch covered only by the remains of the amniotic sac. Further remnants of the amniotic sac, brownish black in colour were found on the posterior abdominal wall the uero-vesical pouch the descending and pelvic colons the transverse colon and omentum, the ascending colon and the peritoneum lining the abdominal wall. The peritoneum was thickened and dark in colour. The abdominal incision had opened into the amniotic sac, but the latter had evidently ruptured prior to the operation. The membranes attached to the placenta maintained their normal colour and had fallen over its upper surface like a cover. The amniotic fluid had evidently become absorbed, there being only some dark sanguinous fluid in Douglas's pouch. Thus although the amniotic sac had ruptured prior to the operation it was not difficult to reconstruct the arrangement of parts. (See illustration.) Moreover it was interesting to note that although the foetus was dead and its skin beginning to peel there were no adhesions of intestine or omentum to prevent its rapid and easy extraction. The small intestine seemed to be packed away in the upper part of the abdominal cavity. Some old blood clot was also cleared out of the uero-vesical pouch and as much of the amniotic sac as was readily detachable was removed. Two large drainage-tubes were introduced into Douglas's pouch and brought out at the lower end of the wound while a veil of gauze was inserted above the tubes to assist in isolating the area to be drained. The abdominal wall was then closed and the dressings were applied. The patient bore the operation well and her pulse became slower and better after the foetus and uterus had been removed. It was at the end of the operation whereas her average rate had lately varied between 120 and 150. Her good condition was largely due to the fact that the total blood loss during the operation probably did not amount to more than a tablespoonful. The anaesthetic was administered by Dr. Lambert whilst Dr. C. M. Penfield rendered me valuable assistance at the operation.

After the operation.—At my visit on the day following the operation the woman looked better and expressed herself as feeling better. The pulse-rate was 95. She had had no sickness or abdominal distension. Her tongue was dry and the complexion of her face all her general condition was as good as

could be expected after such a severe operation. On the next day her general condition was much the same. I did not see her again, but was informed on the fifth day after the operation that her condition was very bad, and she gradually sank and died. For 12 hours previous to her death she was almost maniacal, shouting and exhibiting extreme restlessness. She had had no sickness since the operation. There had been no abdominal discomfort and the bowels acted well. A post-mortem examination was not permitted.

Description of the specimen.—The parts removed consisted of the foetus and placenta together with the uterus removed by supravaginal hysterectomy. The foetus was a female weighing 7 lb. and had reached full development within the abdominal cavity of the mother. It measured 14 inches from the vertex to the coccyx. The trunk and limbs were

Drawing illustrating the relations of the foetus and placenta.

D.C. descending colon C. amniotic sac P. placenta U. uterus.

perfectly developed, but the head was enlarged suggesting early hydrocephalus. The skin of the trunk was beginning to peel and was readily separable on handling whilst it was also undergoing colour changes, bluish black and greenish yellow, indicating the presence of decomposition. The umbilical cord 15 inches in length was normally developed and was attached to a large well formed placenta. The attachment of the umbilical cord was eccentric, being situated towards the left side. The main placental mass was perched like a cap on the upper and back part of the uterus whilst it spread laterally outwards and still more downwards so as to hide completely the uterine surface. The main placental mass measured transversely 5 inches antero-posteriorly 3 inches, whilst the vertical measurement was 6 inches. The two layers chorion and amnion could be demonstrated in the membranes attached to the placenta. Owing to the peculiar arrangement of the membranes there was a part of the placenta at its lower extremity to which the amniotic sac was not attached. This part gradually faded away on the lower segment of the uterus posteriorly. The appearance of the placenta was otherwise normal, and it was firmly inserted on to the posterior surface of the body and fundus of the uterus. The uterus was enlarged and was as sized about the size of a five months' pregnancy but since immersion in formalin it had contracted considerably. Its walls were about 1 inch in thickness and its cavity, polypus about the size of a walnut, springing from the postero-lateral wall on the right side. Did the polypus interfere with the occurrence of intra uterine pregnancy? Thrombotic changes had taken place in the blood vessels, especially on the right side, which tended to diminish the haemorrhage at the operation. The uterine artery on the right side was not identified.

The right side which was not identified was probably connected with the placenta.
The amniotic sac, which was not identified, was probably connected with the placenta.

INDICATIONS AND CONTRA-INDICATIONS IN THE PNEUMOTHORAX TREATMENT OF PULMONARY TUBERCLE

By CLIVE RIVIERE M D LOND, F R C P LOND,
PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE
CHEST VICTORIA PARK E. AND TO THE EAST LONDON HOSPITAL
FOR CHILDREN, SHADWELL, E

In the year 1821 a distinguished British physiologist, James Carson of Liverpool was urging on a seemingly apathetic profession the application of the newly recognised elasticity of the lung to practical therapeutic uses. He pointed out the serious obstacle which was presented by the physical state of the lung its condition of extension, its elasticity, and its constant movement, to the healing of injury within it and recommended its collapse to counteract these influences. Thereby he declared, 'the diseased part would be placed in a quiescent state, receiving little or no disturbance from the movements of respiration, which would be performed solely by the other lung, and the divided surfaces would be brought into close contact by the same resilient power which before had kept them asunder. A wound or abscess in the lung would be placed in circumstances at least as favourable to the healing process as the same affections on any other part of the body.' He proved by experiment on rabbits that animals could live quite well with one lung collapsed, and recommended the treatment for 'consumption,' which, he pointed out, was often found in one lung only in the earlier stages. 'In those cases in which the disease is placed in one of the lungs only the remedy would appear to be simple, safe and complete.'

Nearly a century has gone by and the brilliant foresight of Carson has at length received full recognition, not that so simple a theory as Carson put forward can be held fully to explain the value of pulmonary collapse in the treatment of phthisis, though the local effects be foreshadowed as by no means of negligible importance. The tuberculosis literature of the world has for the past five years concerned itself above all else with the brilliant results of the pneumothorax treatment of phthisis. But it is the continent and America that have supplied almost exclusively this literature. In the British Isles it must be admitted, the treatment has hitherto provoked but little general interest and the prophet Carson has received among his own countrymen just that amount of honour which the world's history might have led us to anticipate. A small band of pioneers among whom the names of Colebrook, Lillingston Vere Pearson, and Rhodes deserve special mention, have indeed long since planted the seed among us but the harvest has been small and the tuberculous Briton has been deprived, hitherto, of the blessings which his brilliant countryman promised a century ago and which the remainder of the phthisical world now enjoys.

Since the success of pneumothorax treatment is bound up, above all else, in the selection of suitable cases I have thought it worth while to put together here some of the general indications and contra indications for this treatment, and therewith to present a description of a particular class of case where pneumothorax therapy seems peculiarly indicated and leads especially to brilliant results. We may conveniently start with a consideration of these cases.

Clinically Unilateral Tuberculosis

It is one may suppose common knowledge that the classical case for pneumothorax treatment is one of considerable one-sided disease, with the other lung clear, or nearly clear to physical examination. Such cases supplied the backbone of this treatment when it is conducted on what I would regard as suitably conservative lines. But where it may be asked are such cases to be found? Experience teaches that in ordinary phthisis of adults disease has usually spread but a little way in one lung before it appears at the opposite apex and there seems but little chance that the better lung can remain clear while the disease on the affected side is spreading itself over the whole lung from apex to base. Clearly these cases of advanced one-sided disease so suitable for pneumothorax treatment must be in many cases at least something other than ordinary apical

phthisis, and their claim for consideration as a distinct group by themselves cannot afford to be disregarded.

For the sake of illustrating certain points characteristic of this group I will refer shortly to some of my hospital pneumothorax material, since this has been in the main composed of cases of advanced one-sided disease. Among 20 such cases, all adults, where the type of disease could be decided with some probability, 17 appeared to stand in a group by themselves and to present certain points of difference from ordinary apical phthisis. All of these cases showed disease covering the whole of one side, and in all of them the good lung was clear or practically clear of signs. In 6 no signs of cavitation were present to physical examination, but moist riles extended from apex to base, in 2 on the right side and in 4 on the left side. In 11 definite cavity signs were present to clinical examination, and in most of these cavitation was considerable, but in all the cavitation showed one striking peculiarity. In no case was it in proximity to the apex of the lung, in all the cavities were found comparatively low down in the lung. Among 4 with right-sided disease, in 3 cavitation was mainly in the axillary region and in the fourth at the base. In the remaining 7 disease was on the left side and in 6 of these cavitation was just outside the heart, about the middle of the lung in the axilla, or just above the heart. In one it was basal. In many of these cases no opportunity occurred for X ray examination before the lung was collapsed, so that the position of cavitation had to be decided by means of physical signs alone. Where X rays were used deep cavitation just outside the lung root was sometimes revealed. In one case a deep cavity just above the heart, near the neck of the left fifth rib gave cavity signs at the surface over the same rib as far away as the axilla. In practically all the cases marked evidence of fibrosis was present and displacement of the heart and mediastinum was demonstrable, especially as would be expected in the cases where cavitation had occurred.

The good lung was clear of stethoscopic signs in all these cases save for the presence of a few doubtful signs, which proved on further observation to have been conducted from the diseased side. The use of the X rays, however, soon dispelled all inclination to describe the better lung as 'healthy' or even as 'good.' In all cases there was present a very definite peribronchial tuberculosis spreading out from the hilus, and often reaching two-thirds or even three-quarters of the way towards the surface. This disease of the better lung appeared to be in most cases an arrested or quiet process. Often it showed itself as a nodulated thickening of the lung reticulum, the nodules being in some cases fine but in others coarser. Where the process was active larger shadows of lung infiltration were visible and the reticulated appearance failed. After some months successful pneumothorax treatment these larger shadows tended to become smaller and denser and gradually to fall into a pattern which followed the lines of the ordinary network of the lung. Unlike cases of apical phthisis where the skiagram shows disease mainly occupying the lung between the root and the apex in these cases the disease is seen to spread out in all directions from the root and often to occupy mainly the middle third of the lung or to branch in two or three directions of which the middle and lower are usually the most strikingly evident.

It appears to be the rule, then, that in these cases, in spite of negative stethoscopic evidence there is present in the better lung a considerable amount of healed or quiescent disease. The appearance of this in a skiagram need in no way deter from pneumothorax treatment as long as the appearance suggests a quiet type of disease and physical signs are absent, for the results of treatment are commonly as good in these cases as if the lung was really healthy. With regard to the absence of physical signs, it is truly remarkable how near the surface of the lung this central disease even of active type may reach without either moist sounds or alteration of breath sounds giving notice of its presence. As far as the stethoscope gives warning we might be dealing with a healthy organ fully clear of disease. And in this respect these cases remind us at once of certain other tuberculous conditions where in spite of central disease stethoscopic signs are absent over both lungs instead of as in the cases just described, over one side of the chest.

Hilus tuberculosis in children.—This is a condition where tuberculosis of chest glands is associated with a tuberculous

A historical study of the subject of abdominal pregnancy reveals the interesting fact that the older writers divide what they termed 'ventral pregnancies' into two classes, the primary and the secondary. By primary is meant that class in which the foetus is developed at once in the peritoneal cavity while in the second class are included all those cases in which the sac originally located in the tube or ovary has ruptured and the escaped foetus goes on developing in the abdomen. It should further be added that they believed in the existence of ovarian pregnancy. I have no doubt their views will be substantiated by further research and experience, as has already been accomplished by the study of ovarian pregnancy and it will be established that although primary abdominal pregnancy is rare yet that it does occur in the human female.

I do not say the example here recorded is or is not a primary abdominal pregnancy, for I can neither prove it nor disprove it, but I place it on record as a contribution towards the elucidation of this subject. Let me, however, again refer to one or two points in the clinical history. With the exception of the illness at the commencement of her pregnancy the patient had no acute pain, sudden illness or fainting during the whole course of her pregnancy, and her husband informed me that she was remarkably well, and in this regard the history corresponds closely with that of the case recorded by the late Mr J W Taylor in the Transactions of the Obstetrical Society of London for 1897. He concluded that a "gradual erosion or giving way of the upper part of the tube had permitted the escape of the ovum into the abdominal cavity. In other words, his theory was made to fall into line with the views as to causation which were upheld at that time. But with our present knowledge it is equally feasible to regard his case as one of primary abdominal pregnancy, a view which is strengthened by the clinical history. The absence of abdominal illness at any time during the course of such a pregnancy is, in my opinion, strong presumptive evidence in favour of a primary abdominal implantation of the ovum.

Now Dr Huston assures me that during the illness in August and September 1915 when he was in attendance, and which has already been mentioned in the previous history of the case here recorded there was no suggestion of any abdominal trouble. Moreover, from a study of clinical histories it would appear that the abdominal foetus has had a severe struggle to maintain its independent existence. It is, however remarkable that a woman can enjoy good health during the gestational period when the foetus is in her abdominal cavity covered only by its amniotic sac. Some recorded examples of abdominal pregnancy speak of the foetus being free amongst the intestines. This I believe to be a faulty observation for I should imagine that no foetus would reach its full development unless enclosed in a sac and as the latter is as a rule opened when the abdominal cavity is opened it is easy to conclude that the foetus is lying free. Further, when the sac ruptures or the liquor amnii becomes absorbed, why do not the omentum and intestines adhere to the decaying foetus? When the gestation is much prolonged this adhesion has been observed but it would appear that for a long time no adhesions are formed.

Again, what is the explanation of the rush of waters when false labour set in? The amount was sufficient to soak the bedclothes when the woman returned to bed. Did it come through the Fallopian tube or tubes? In Taylor's case what he took to be the fimbriated end of the Fallopian tube was incorporated with the placenta, but the remainder of the tube could not be traced. I have not been able to trace any connexion between the right Fallopian tube and the placenta, but the tube on the left side was free and doubtless patent. Owing to the rapid growth of the placenta it is easy to imagine that a delicate structure like the Fallopian tube could be so to speak overgrown and incorporated with the placental mass and thus I think is worthy of consideration as an alternative to the view that the destruction has been due to tubal rupture.

The ovary on the right side could not be identified but it is quite possible too that this organ could be destroyed by the placental growth. The ovary was smaller than that on the left side and was sclerosed and adhered to the broad ligament. Whether this had resulted from any interference with the ovarian circulation it is impossible to say. The left ovary was free and of normal size and was covered on its

inner surface by the amniotic sac. The external surface of the left ovary and the fimbriated end of the left tube were outside the amniotic sac at least; no trace of the sac was observed on them.

Surgical Treatment

I have already recorded an example of abdominal pregnancy in which a living fetus at $4\frac{1}{2}$ months was successfully removed. The placenta was implanted in the posterior surface of the uterus the floor of Douglas's pouch and on the pelvic colon. Previous to the removal of the placenta the main sources of vascular supply were controlled including a large artery coursing down the posterior surface of the uterus and then the placenta was rapidly separated and the placental site at once plugged with gauze, the raw surface on the intestine was treated by folding in the wall of the gut and over stitching with catgut. A gauze plug was left in the pelvis and was subsequently withdrawn during convalescence.

Thus in dealing with the placenta two important principles should be followed (1) to control the main vascular supply by preliminary ligature, and (2) to separate the placenta rapidly

In the case here recorded the position of the placenta was ideal as regards surgical treatment, for by means of a supravaginal hysterectomy the vascular supply was controlled and the placenta itself removed. It was the toxic condition of the patient that militated against her ultimate recovery. The advice to wait until the child is dead and the placenta thrombosed is hardly in harmony with the trend of modern surgery, moreover, the presence of infection is a serious factor which may mar the success of a future operation. I think, therefore, that if the principle of preliminary ligation of the vascular supply be properly carried out there should be little difficulty in dealing with the living placenta.

When an abdominal pregnancy is diagnosed with a living child, should we wait until the child is viable? It is true that living children have been extracted and have survived but there is no evidence concerning their future growth and development, and as many of the children in recorded cases have possessed deformities I believe the best practice is to operate at once as soon as the diagnosis is made.

In conclusion, it is a source of great satisfaction to find that it is from investigations made in this country that many of the interesting problems in the life history of ectopic gestation have been unravelled, and that their elucidation forms a brilliant chapter in the history of British gynaecology. The name of Lawson Tait will for ever stand forth as a pioneer in the surgical treatment

A MEDICAL LIBEL ACTION.—Mr F E Forward, Mr F J W Sass and Dr W D Higson were plaintiffs in a recent action in the King's Bench Division in which they claimed damages for libel against the Women's Press. Dr F Moxon, Mrs E Pankhurst, Mrs M Tuke, Mrs N D Fox and Mrs B Sanders who were sued personally and on behalf of the Women's Social and Political Union, the Scottish Newspaper Publishing Company Limited and Messrs W H Smith and Son. The libels complained of were published in the *Suffragette* and made what were in effect charges of cruelty in respect of forcible feeding administered to women prisoners on hunger strike in Holloway Prison of which the plaintiffs at the material time were medical officers. Dr Moxon the author of part of the matter complained of at first sought to justify but later wrote a letter from France where he was serving with drawing all charges against the plaintiffs. The defendants of the Women's Press, Mrs Pankhurst, Mrs Tuke, Mrs Fox and Mrs Sanders were struck out owing to their refusal to obey an order of the court. The Scottish newspaper firms having apologised a verdict was returned with regard to Messrs W H Smith upon which judgment was entered for the defendants and damages were assessed against the other plaintiffs. The plaintiffs are a group of persons of real which ample evidence has gone to show and which was indeed a foregone conclusion. The defendants were unbalanced or deceived people who discriminated against accusers against members of the medical profession during the suffragette's martyrdoms.

INDICATIONS AND CONTRA-INDICATIONS IN THE PNEUMOTHORAX TREATMENT OF PULMONARY TUBERCLE

By CLIVE RIVIERE, M D LOND, F R C P LOND,

PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST VICTORIA PARK E. AND TO THE EAST LONDON HOSPITAL FOR CHILDREN SHADWELL, E

In the year 1821 a distinguished British physiologist, James Carson of Liverpool, was urging on a seemingly apathetic profession the application of the newly recognised elasticity of the lung to practical therapeutic uses. He pointed out the serious obstacle which was presented by the physical state of the lung, its condition of extension, its elasticity, and its constant movement, to the healing of injury within it and recommended its collapse to counteract these influences. Thereby he declared, 'the diseased part would be placed in a quiescent state, receiving little or no disturbance from the movements of respiration which would be performed solely by the other lung, and the divided surfaces would be brought into close contact by the same resilient power which before had kept them asunder. A wound or abscess in the lung would be placed in circumstances at least as favourable to the healing process as the same affections on any other part of the body.' He proved by experiment on rabbits that animals could live quite well with one lung collapsed, and recommended the treatment for 'consumption,' which, he pointed out, was often found in one lung only in the earlier stages. 'In those cases in which the disease is placed in one of the lungs only, the remedy would appear to be simple, safe and complete.'

Nearly a century has gone by and the brilliant foresight of Carson has at length received full recognition, not that so simple a theory as Carson put forward can be held fully to explain the value of pulmonary collapse in the treatment of phthisis, though the local effects he foreshadowed are by no means of negligible importance. The tuberculosis literature of the world has for the past five years concerned itself above all else with the brilliant results of the pneumothorax treatment of phthisis. But it is the continent and America that have supplied almost exclusively this literature. In the British Isles, it must be admitted, the treatment has hitherto provoked but little general interest, and the prophet Carson has received among his own countrymen just that amount of honour which the world's history might have led us to anticipate. A small band of pioneers among whom the names of Colebrook, Lillingston Vere Pearson, and Rhodes deserve special mention, have, indeed, long since planted the seed among us but the harvest has been small and the tuberculosis Briton has been deprived hitherto of the blessings which his brilliant countryman promised a century ago and which the remainder of the phthisical world now enjoys.

Since the success of pneumothorax treatment is bound up, above all else, in the selection of suitable cases, I have thought it worth while to put together here some of the general indications and contra indications for this treatment, and therewith to present a description of a particular class of case where pneumothorax therapy seems peculiarly indicated and leads especially to brilliant results. We may conveniently start with a consideration of these cases.

Clinically Unilateral Tuberculosis

It is one may suppose, common knowledge that the classical case for pneumothorax treatment is one of considerable one-sided disease with the other lung clear, or nearly clear, to physical examination. Such cases supplied the earliest material for treatment, and they still form the backbone of this treatment when it is conducted on what I would regard as suitably conservative lines. But where it may be asked are such cases to be found? Experience teaches that in ordinary phthisis of adults disease has usually spread but a little far in one lung before it appears at the opposite apex and there seems but little chance that the better lung can remain clear while the disease on the affected side is spreading itself over the whole lung from apex to base. Clearly these cases of advanced one-sided disease so suitable for pneumothorax treatment must be in many cases at least something other than ordinary apical

phthisis, and their claim for consideration as a distinct group by themselves cannot afford to be disregarded.

For the sake of illustrating certain points characteristic of this group I will refer shortly to some of my hospital pneumothorax material, since this has been in the main composed of cases of advanced one-sided disease. Among 20 such cases, all adults, where the type of disease could be decided with some probability, 17 appeared to stand in a group by themselves and to present certain points of difference from ordinary apical phthisis. All of these cases showed disease covering the whole of one side, and in all of them the good lung was clear or practically clear of signs. In 6 no signs of cavitation were present to physical examination but moist riles extended from apex to base, in 2 on the right side and in 4 on the left side. In 11 definite cavity signs were present to clinical examination, and in most of these cavitation was considerable, but in all the cavitation showed one striking peculiarity. In no case was it in proximity to the apex of the lung, in all the cavities were found comparatively low down in the lung. Among 4 with right-sided disease, in 3 cavitation was mainly in the axillary region and in the fourth at the base. In the remaining 7 disease was on the left side and in 6 of these cavitation was just outside the heart about the middle of the lung, in the axilla or just above the heart. In one it was basal. In many of these cases no opportunity occurred for X ray examination before the lung was collapsed, so that the position of cavitation had to be decided by means of physical signs alone. Where X rays were used deep cavitation just outside the lung root was sometimes revealed. In one case a deep cavity just above the heart, near the neck of the left fifth rib gave cavity signs at the surface over the same rib as far away as the axilla. In practically all the cases marked evidence of fibrosis was present, and displacement of the heart and mediastinum was demonstrable, especially, as would be expected in the cases where cavitation had occurred.

The good lung was clear of stethoscopic signs in all these cases save for the presence of a few doubtful signs, which proved on further observation to have been conducted from the diseased side. The use of the X rays however, soon dispelled all inclination to describe the better lung as 'healthy' or even as 'good.' In all cases there was present a very definite peribronchial tuberculosis spreading out from the hilus and often reaching two-thirds or even three-quarters of the way towards the surface. This disease of the better lung appeared to be in most cases an arrested or quiet process. Often it showed itself as a nodulated thickening of the lung reticulum, the nodules being in some cases fine but in others coarser. Where the process was active larger shadows of lung infiltration were visible and the reticulated appearance failed. After some months successful pneumothorax treatment these larger shadows tended to become smaller and denser and gradually to fall into a pattern which followed the lines of the ordinary network of the lung. Unlike cases of apical phthisis where the skiagram shows disease mainly occupying the lung between the root and the apex in these cases the disease is seen to spread out in all directions from the root and often to occupy mainly the middle third of the lung, or to branch in two or three directions of which the middle and lower are usually the most strikingly evident.

It appears to be the rule, then, that in these cases, in spite of negative stethoscopic evidence, there is present in the better lung a considerable amount of healed or quiescent disease. The appearance of this in a skiagram need in no way deter from pneumothorax treatment as long as the appearance suggests a quiet type of disease and physical signs are absent for the results of treatment are commonly as good in these cases as if the lung was really healthy. With regard to the absence of physical signs, it is truly remarkable how near the surface of the lung this central disease even of active type, may reach without either moist sounds or alteration of breath sounds giving notice of its presence. As far as the stethoscope gives warning we might be dealing with a healthy organ fully clear of disease. And in this respect these cases remind us at once of certain other tuberculous conditions where, in spite of central disease, stethoscopic signs are absent over both lungs instead of, as in the cases just described, over one side of the chest. This is the condition where tuberculous glands is associated with a tuberculosis

A historical study of the subject of abdominal pregnancy reveals the interesting fact that the older writers divide what they termed 'ventral pregnancies' into two classes, the primary and the secondary. By primary is meant that class in which the fœtus is developed at once in the peritoneal cavity while in the second class are included all those cases in which the sac originally located in the tube or ovary has ruptured and the escaped fœtus goes on developing in the abdomen. It should further be added that they believed in the existence of ovarian pregnancy. I have no doubt their views will be substantiated by further research and experience, as has already been accomplished by the study of ovarian pregnancy and it will be established that although primary abdominal pregnancy is rare, yet that it does occur in the human female.

I do not say the example here recorded is or is not a primary abdominal pregnancy for I can neither prove it nor disprove it, but I place it on record as a contribution towards the elucidation of this subject. Let me, however, again refer to one or two points in the clinical history. With the exception of the illness at the commencement of her pregnancy the patient had no acute pain, sudden illness, or fainting during the whole course of her pregnancy, and her husband informed me that she was remarkably well, and in this regard the history corresponds closely with that of the case recorded by the late Mr J W Taylor in the Transactions of the Obstetrical Society of London for 1897. He concluded that a "gradual erosion or giving way of the upper part of the tube had permitted the escape of the ovum into the abdominal cavity." In other words, his theory was made to fall into line with the views as to causation which were upheld at that time. But with our present knowledge it is equally feasible to regard his case as one of primary abdominal pregnancy, a view which is strengthened by the clinical history. The absence of abdominal illness at any time during the course of such a pregnancy is, in my opinion, strong presumptive evidence in favour of a primary abdominal implantation of the ovum.

Now Dr Huston assures me that during the illness in August and September, 1915 when he was in attendance, and which has already been mentioned in the previous history of the case here recorded, there was no suggestion of any abdominal trouble. Moreover, from a study of clinical histories it would appear that the abdominal foetus has had a severe struggle to maintain its independent existence. It is however remarkable that a woman can enjoy good health during the gestational period when the foetus is in her abdominal cavity covered only by its amniotic sac. Some recorded examples of abdominal pregnancy speak of the foetus being free amongst the intestines. This I believe to be a faulty observation for I should imagine that no foetus would reach its full development unless enclosed in a sac, and as the latter is as a rule opened when the abdominal cavity is opened it is easy to conclude that the foetus is lying free. Further, when the sac ruptures or the liquor amni becomes absorbed, why do not the omentum and intestines adhere to the decaying foetus? When the gestation is much prolonged this adhesion has been observed, but it would appear that for a long time no adhesions are formed.

Again, what is the explanation of the rush of waters when false labour set in? The amount was sufficient to soak the bedclothes when the woman returned to bed. Did it come through the Fallopian tube or tubes? In Taylor's case what he took to be the fimbriated end of the Fallopian tube was incorporated with the placenta but the remainder of the tube could not be traced. I have not been able to trace any connexion between the right Fallopian tube and the placenta, but the tube on the left side was free and doubtless patent. Owing to the rapid growth of the placenta it is easy to imagine that a delicate structure like the Fallopian tube could be so to speak overgrown and incorporated with the placental mass and thus, I think, is worthy of consideration as an alternative to the view that the destruction has been due to tubal rupture.

The ovary on the right side could also be identified but it is quite possible too that this organ could be destroyed by the placental growth. The ovary was smaller than that on the left side and was sclerosed and adhered to the broad ligament. Whether this had resulted from any interference with the ovarian circulation it is impossible to say. The left ovary was free and of normal size and was covered on its

inner surface by the amniotic sac. The external surface of the left ovary and the fimbriated end of the left tube were outside the amniotic sac at least no trace of the sac was observed on them.

Surgical Treatment

I have already recorded an example of abdominal pregnancy in which a living fetus at 4½ months was successfully removed. The placenta was implanted in the posterior surface of the uterus, the floor of Douglas's pouch and on the pelvic colon. Previous to the removal of the placenta the main sources of vascular supply were controlled, including a large artery coursing down the posterior surface of the uterus, and then the placenta was rapidly separated and the placental site at once plugged with gauze, the raw surface on the intestine was treated by folding in the wall of the gut and over stitching with catgut. A gauze plug was left in the pelvis and was subsequently withdrawn during convalescence.

Thus in dealing with the placenta two important principles should be followed (1) to control the main vascular supply by preliminary ligature, and (2) to separate the placenta rapidly

In the case here recorded the position of the placenta was ideal as regards surgical treatment, for by means of a supravaginal hysterectomy the vascular supply was controlled and the placenta itself removed. It was the toxic condition of the patient that militated against her ultimate recovery. The advice to wait until the child is dead and the placenta thrombosed is hardly in harmony with the trend of modern surgery, moreover, the presence of infection is a serious factor which may mar the success of a future operation. I think, therefore, that if the principle of preliminary ligation of the vascular supply be properly carried out there should be little difficulty in dealing with the living placenta.

When an abdominal pregnancy is diagnosed with a living child, should we wait until the child is viable? It is true that living children have been extracted and have survived but there is no evidence concerning their future growth and development, and as many of the children in recorded cases have possessed deformities I believe the best practice is to operate at once as soon as the diagnosis is made.

In conclusion, it is a source of great satisfaction to find that it is from investigations made in this country that many of the interesting problems in the life history of ectopic gestation have been unravelled, and that their elucidation forms a brilliant chapter in the history of British gynaecology. The name of Lawson Tait will for ever stand forth as a pioneer in the surgical treatment

A MEDICAL LIBEL ACTION—Mr F E Forward, Mr F J W Sass and Dr W D Higson were plaintiffs in a recent action in the King's Bench Division in which they claimed damages for libel against the Women's Press. Dr F Moxon, Mrs E Pankhurst, Mrs M Tuke Mrs N D Fox and Mrs B Sanders who were sued personally and on behalf of the Women's Social and Political Union the Scottish Newspaper Publishing Company Limited and Messrs W H Smith and Son. The libels complained of were published in the *Suffragette* and made what were in effect charges of cruelty in respect of forcible feeding administered to women prisoners on hunger strike in Holloway Prison of which the plaintiffs at the material times were medical officers. Dr Moxon the author of part of the matter complained of at first sought to justify but later wrote a letter from France where he is serving with drawing all charges against the plaintiffs. The defences of the Women's Press Mrs Pankhurst Mrs Tuke Mrs Fox and Mrs Sanders were struck out owing to their refusal to obey an order of the court. The Scottish Newspaper Co having apologised a venire was returned with regard to Messrs W H Smith upon which judgment was entered for them and damages were assessed against the other defendants for £750 to be divided equally among the three plaintiffs. The plaintiffs are to be compensated upon a result which amply vindicates their good name and which was indeed a foregone conclusion. The unethical unbalanced or deceived people who disseminate libellous accusations against members of the medical profession during the suffrage riots may possibly take warning.

somewhat of an enigma in pneumothorax treatment that, while in most cases disease in the good lung improves, in some disease is lighted up and increases. It has seemed to me probable that it is particularly in apical cases that the latter experience is apt to arise, disease being generally fresh and active in place of the quiet and long standing lesions of hilus tuberculosis.

Where, then, must the indications and contra indications be drawn in the case of apical phthisis? Forlanini tells us to think of pneumothorax therapy as soon as ulcerative processes appear in the lungs and this for the following reasons: (a) The probability of disease remaining one sided becomes smaller the further disease advances, (b) the more advanced the disease the more is the likelihood of adhesions appearing and limiting, or altogether preventing, this treatment, (c) the more circumscribed the disease the more assurance is there that the lung will expand and functionate perfectly after the treatment is completed, and (d) the more advanced the disease the greater the risk of that fatal accident, perforation of the lung. These warnings against delay are applicable, though in a different degree, to hilus tuberculosis no less than to apical phthisis, but in hilus tuberculosis it commonly happens that the extent of disease has only been realised when it is already far advanced. In apical phthisis the most important of these warnings is the first—namely, the likelihood of active disease appearing in the better lung and jeopardising, or altogether preventing, treatment by artificial pneumothorax. As a rule this will have happened before the other three warnings need to be seriously taken to heart so that our main consideration must be the state of the other lung.

The other lung.—Most writers are of opinion that active disease in the opposite lung is a distinct contra indication for treatment, inactive or quiet disease is considered no bar. These qualifications are obviously open to various interpretations, the decision must always be one directed to the individual case. Zink found that even arrested lesions which extended beyond the upper lobe generally got worse. Spengler regards a fresh, active process of the other side as an absolute contra indication. Weiss, on the other hand, remarks that active lesions may sometimes be favourably influenced, he has at least seen them uninfluenced. Forlanini holds that limited active lesions may improve. He has described also two cases with double lesions too advanced to treat, but which later developed spontaneous pneumothorax. This was kept up artificially and resulted in a great improvement in both cases, proceeding in one to complete recovery. On this account he suggests that some cases with double lesion should be given the chance and he and others have treated both lungs alternatively with some measure of success. In this country, however, pneumothorax treatment must be regarded as still on its trial, and it should on that account be reserved as far as possible for cases strictly suitable. Its use as a last resort in cases well nigh hopeless is at this stage of its history greatly to be deprecated. Not only will it at times defeat its own purpose unless chosen with the greatest circumspection and actually hurry such cases to death, but also its failure to relieve is bound to bring it into undeserved discredit and thereby deprive other suitable cases from the lasting benefits it is able to confer. Though it cannot perhaps be refused in certain cases where the chances are small, these important disqualifications should be borne in mind before consent is given to its trial.

Early phthisis.—A more important disqualification, in my opinion, exists in the case of early phthisis. The use of pneumothorax therapy in these cases can be shown on many grounds to be contra indicated. In the first place it is unnecessary since early phthisis is a most curable disease by many other methods of treatment. In the second place it is inexpedient in that it brings with it risks and the chance of serious complications out of all relation to the benefits it can confer. Pleural shock and gas embolism can perhaps be considered but infinitesimal risks where modern knowledge is properly applied, but they cannot be altogether eliminated, the chances of pleural effusion on the other hand and the troublesome deformities which may follow it cannot in any way be avoided. Such effusions occur altogether in nearly 50 per cent of pneumothorax cases and though the shorter treatment required for slight disease would reduce this percentage yet effusions must occur in many, and expansion of the lung fail or be incomplete in a few. Moreover the lung may become totally adherent and the patient be thereby

deprived of this treatment at a later stage, if it should then be required.

Having considered, then, shortly the extremes which bound the limits of suitability on either hand we may return to the recommendation of Forlanini to think of pneumothorax treatment as soon as ulcerative processes appear in the lungs. Cases of cavitation of anything but small extent, and cases where an infiltrative process progresses in spite of a fair trial of sanatorium treatment—these are the general indications in cases of apical phthisis. Here we are speaking of chronic or fibro-caseous disease, the acuter forms of tubercle need special and separate consideration.

Acute Forms of Tuberculosis

Miliary tuberculosis does not, of course, come into consideration. The broncho-pneumonic forms are commonly so far bilateral that the question of pneumothorax therapy hardly arises. Caseous pneumonic cases are generally one-sided at first, and have received this treatment with varying success at the hands of different operators. Forlanini has not been fortunate in this class of case, but has found that disease always invades the opposite lung. Saugman, however, has had success in a case of consolidation of the whole of one lung. Dumarest also claims a cure in a case of this class. Weiss treated 5 pneumonic cases, in 4 disease appeared on the opposite side, in one case as late as six months after, and death resulted. In the fifth case, which was one of caseous pneumonia on the top of chronic phthisis, recovery occurred. I treated a broncho-pneumonic case involving the whole of one lung, and with a fair amount of active central disease on the opposite side, the patient died of a rapidly developing oedema of the better lung. I have also treated a case of caseous pneumonia with the best possible results up to the present. I give brief particulars of the case.

The patient aged 19, had been admitted to the London Hospital on Jan 21st, 1915, with a diagnosis of lobar pneumonia. Acute onset two weeks previously, with rigor, pains in the right chest, dyspnoea, and cough. There was consolidation of the whole of the right lung. Temperature swinging between 100° and 101.5° or 102° F often highest in the early morning, pulse 100-112, respirations 28-32, wasting. Tubercle bacilli found in the sputum on Jan 28th. Returned home in *status quo* Feb 24th.

The patient was seen by me early in March, 1915. He was admitted to hospital on March 10th wasted and ill, weight 6 st 13 lb, temperature 99°-100°, often larger fluctuations, occasionally of reversed type, pulse, 120, respirations 28. There was consolidation with crepitations over the whole right front and lower two-thirds back. Large cavitation at base. Left side clear, save for some crepitations outside the heart's apex and base behind.

On March 23rd an artificial pneumothorax was initiated on the right side and soon made complete with displacement of the heart one inch outside the left nipple. Intrapleural pressure was kept at ± 10 to $+12$ cm H₂O mean pressure, but at a later stage reduced to -7 or 8 . The lung appeared very stiff and solid to X rays and did not collapse to the usual dimensions. The temperature was normal by April 10th, but the pulse not until the middle of May. The patient began to leave his bed on April 25th. He lost a few pounds in weight up to mid-June and afterwards gained steadily. His general health progressed steadily and by August the left side was entirely clear. He was then by mistake set to light gardening work. Tubercle bacilli began to appear and to increase in the sputum of which there was still a trace, crepitations returned on the left side and by Oct 19th there were 3 inches of fluid in the right pleural cavity, rising to 5 inches in November and afterwards remaining stationary. The fluid examined by Dr Roodhouse Glorne was of clear amber appearance, it contained 35 per cent of protein, a small deposit of endothelial cells was sterile and contained no tubercle bacilli. No antibodies present. The patient has since remained well up and about with normal temperature sputum practically absent, pulse, 88-92, respiration 24. His weight on Feb 2nd 1916, was 7st 10lb 3oz., a gain of 11 lb since admission. Some fluid remains in the right pleural cavity, but as commonly happens in these cases it causes no inconvenience and will be left to absorb. The patient has received in all 23 fillings of nitrogen in the ten months during which he has been under treatment.

A B.—By the end of March fluid was entirely absorbed weight 8 st. 2 lb on leaving hospital in April. Has remained well and at work since.

Hæmoptysis

There remains only hæmoptysis as an indication for pneumothorax treatment. This may be an emergency

spreading out into the lung. This is often a quiet peribronchial process of both lungs leading to but few and even no symptoms, though at any point a broncho-pneumonic process may arise and more acute disease supervene. In either condition stethoscopic signs of lung disease are generally absent in all but the later stages, and the presence of lung disease apart from X ray examination, can only be presumed on other grounds. The chest signs, such as they are (impairment of note over the right side, right inter-scapular impairment, blowing breath sounds at the apex, &c.), are due to interference with certain lines of communication by glandular enlargement, and not to disease of the lung. In many cases evidence of deep lung disease is given by the presence of the reflex bands of impairment over the back described by me in a recent communication.¹ In adults such cases of hilus tuberculosis with glandular enlargement are uncommon, but they do occur and present similar signs to those outlined above.

Hilus tuberculosis of adults—More commonly in adults a hilus tuberculosis occurs unaccompanied by any manifest glandular enlargement—a condition to which clinicians have hitherto paid but little attention though the radiographer has long recognised it, generally under the title of "peribronchial tuberculosis." This seems to me an unfortunate nomenclature, for though tuberculosis spreading from the hilus is often largely or entirely of peribronchial type, yet a tuberculous peribronchitis may affect any region of the lung and cannot be considered the special prerogative of this central form of disease. The failure of the clinician to recognise this group of cases is due, as a rule, to his failure to diagnose them. In its slighter forms the disease may remain altogether subclinical. In more inveterate attacks it is very commonly of chronic and insidious course, and the main symptom often a progressive dyspnoea associated sometimes with chronic bronchitis and emphysema and with asthmatic attacks. Indeed in many of these cases proof of the tuberculous nature of the disease entirely fails, and the peribronchitis may very well be due to other causes of irritation. In cases more manifestly tuberculous the course, and the appearance on occasions of hæmoptysis, or of sputum containing tubercle bacilli, render the diagnosis of tubercle more certain. But the signs may be of the slightest and readily overlooked in earlier stages. Bronchitic râles are often present, and these may be more marked at, or even confined to, a limited area of the chest. The percussion note to light percussion may be a trifle less good at one apex or all over one side, and Krönig's apical resonance is nearly always narrowed on one or both sides, a most important sign. In addition the reflex bands of impairment described by me and already referred to are invariably present, and point to the presence of deep pulmonary disease which the X rays will generally render manifest.

Now it seems to be a variety of this hilus tuberculosis which supplies these cases of apparent unilateral disease so favourable for treatment by artificial pneumothorax. The spread through the lung is often, in all probability, a slow process marked by exacerbations and periods of arrest, and the surface is reached almost simultaneously all over the chest, giving signs over the whole side. But until this point is reached stethoscopic signs will fail, and the presence of disease must hence be often overlooked, or at least its nature unrecognised. It is probably only in the later stages that the toxæmia is sufficient to overcome tolerance and lead to "reactions" shown in fever and other symptoms and in "focal reactions" whereby the vicious circle of active autotoxic tuberculosis is established under which the patient will soon succumb unless the toxæmia can be arrested. Hence the symptoms in these cases of very widespread but evidently also long standing disease are often of much shorter duration than the amount and nature of disease would seem to warrant. A few months' history is often all that is obtainable in cases with extensive cavitation and with fibrosis leading to marked visceral displacement.

There is good evidence that up to a certain point—namely the point where toxæmia definitely overcomes tolerance—hilus tuberculosis of adults is nearly always a disease of chronic course and favourable outlook and far more amenable to suitable treatment than is apical phthisis. This tendency to arrest and cure shows itself strikingly

even in such advanced cases as come under treatment by artificial pneumothorax. It is but seldom that disease in the better lung, even if this is of moderately active nature fails to improve so soon as auto-inoculation is removed by collapse of its diseased companion organ.

Now, the recognition of unilateral tuberculosis as a clinical entity is no new or original discovery. In 1912 Straub and Otten,² working in von Romberg's clinic published a careful description of this one-sided disease based on a study of 27 cases. Furthermore they recognised its peculiar relationship to pneumothorax treatment and included in their study an analysis of 99 cases treated by Brauer after this method. It will be well to consider shortly their descriptions of this type of disease. The main characteristics on which they laid stress are the fact that the apex is not the oldest focus, and that cavitation does not appear here but deep in the lung and at a lower level. They found that signs first appear over the front of the chest attacking on the right side, the base of the upper lobe, or less commonly the middle and lower lobe and on the left side the base of the upper lobe, especially in proximity to the outer border of the heart. They noted that there was marked tendency to fibrosis and displacement of organs, and that disease ran a more chronic course on the left side than on the right, often proceeding to cavitation without complaint of either cough, sputum, fever, or pain. On the right side they found disease spread through deep parts of the lung towards the axilla, but on the left side it tended at an early stage to reach the surface just above the heart in the second or third space near the sternal border, presenting signs of chronic disease, often with cavitation at this point. They recognised the relationship to hilus tuberculosis of childhood, and traced its development therefrom. Their 27 cases comprised many of early hilus disease in children and young people.

While agreeing in the main with the description of the disease supplied by these authors a different experience on some points has persuaded me that their material and my own is too small to justify any hard and fast delineation of sub types or minor peculiarities. Their main contention, however falls in with my own experience—namely, that there exists such a definite "vom hilus ausgehende" form of disease of different course and different prognosis to so-called "apical phthisis" and that certain more virulent of such cases form the most notable material for treatment by artificial pneumothorax. An account of the more characteristic distribution, and hence the easier recognition of left-sided disease of this type an attempt was made by Straub and Otten to trace these cases among other tuberculous material within their reach. Among 135 cases of pulmonary tuberculosis examined by them 10 or 7.4 per cent were left-sided cases of this type. Brauer's 99 pneumothorax cases showed 48 on the right side and 51 on the left. Among the latter, 17 or 33 per cent were certainly of this type, and a further 18 or 35.3 per cent, were very probably so. The results of pneumothorax treatment among the left-sided cases are analysed as follows—

	Much improved	Improved	No change	Died
Hilus cases .. 10	53.8%	5 = 29.4%	—	2 = 11%
Probably hilus 10	55.5%	4 = 22.2%	—	2 = 10%
Not hilus .. 5	31.3%	3 = 18.7%	2 = 12.5%	6 = 37.5%

It is interesting to place beside these figures although not strictly comparable the results of ordinary hygienic dietetic treatment among Straub and Otten's 27 cases.

	Much improved	Improved	No change	Died
All cases .. 27	10.5%	7 = 25.9%	3 = 11.1%	7 = 25.9%

Apical Phthisis

After this brief description of a class of cases of supreme importance to the pneumothorax therapy we may pass on to the indications for collapse of the lung in cases of ordinary apical phthisis. Here two points of contrast to the cases already described at once come into notice. First, cases cannot be allowed to advance far within the apex, a large becoming involved in active disease. Secondly, there is reason to suppose that disease in the good lung is a serious threat to success of treatment in apical phthisis. It is in the case of hilus tuberculosis. It has always been

Lesions of the visual path have been by no means uncommon during the present war, we have ourselves seen numerous examples of cortical and of subcortical lesions and of lesions of the optic radiations. Such cases present features of interest which have been studied by many observers. Lesions of the optic tract which are commonly associated with signs of pyramidal affection from injury to the adjacent crus cerebri, are far less common, an excellent example however has been published by Maie and Chatehn.¹ Lesions of the chiasma itself without implication of the long tracts of the brain stem are, however, still rarer.

In the foregoing case the presence of an apparent left-sided hemianopia seemed at first to indicate a simple lesion of the right optic tract somewhere behind the chiasma. The occurrence of the hemiopic pupillary reaction further limited the probable position of the lesion to a spot somewhere below the primary reflex visual centre in the right external geniculate body

FIG 1.

including the central fixation point of each eye. It winds backwards, around the outer side of the crus cerebri, to the primary optic centre in the external geniculate body and anterior corpus quadrigeminum. The farther backward

FIG 3

Visual field of the left eye on March 6th.

FIG 4

The same on March 17th

FIG 5

The same on March 21st.

Further observations, however showed that it was not so simple as this.

Let us recall for a moment some points in the anatomy of the visual path. The fibres from each optic nerve run backwards to the optic chiasma. Here a partial decussation occurs (see Fig 6) so that the fibres from the right halves of both retinas—i.e. from the left halves of both visual fields—after traversing the chiasma emerge behind it to form the right optic tract. Similarly with the fibres from the left halves of the retina, which enter the left optic tract. The macular or central visual fibres from the macula lutea of each eye are distributed in both optic tracts. As the chiasma is approached the fibres from the nasal halves of the retina (temporal halves of the fields) tend to become ventral in position while those from the temporal halves tend to become dorsal. The macular bundle occupies a central position. The optic tract emerging from the chiasma behind contains visual fibres from the whole central lateral half of both visual fields.

FIG 6

Diagram indicating the position of the lesion in the optic chiasma.

course of the visual fibres to the cortical half vision centre in the calcarine cortex does not concern us here.

In our case the apparent left-sided hemianopia together with the hemiopic pupillary reaction seemed at first sight to point to an ordinary straightforward lesion of the right optic tract. More careful study, however, showed that this was not the case. Firstly the boundary between the blind and the seeing area of the visual field is not vertical, as in an ordinary tract lesion but oblique. That is to say both lateral halves of the visual field are affected, including nearly the whole of the left field and a small sector of the right. The incompleteness of the affection of the left field is further evidenced by the fact that there is also a small area of recovery extending outwards from the fixation point.

Fig 6 is a diagram indicating the position of the lesion in this case. The lesion affects mainly the fibres destined for the right optic tract. Some of them, however, have escaped—viz., those corresponding to the upper and mesial sector of the blind field—also a smaller number corresponding to the area just above the horizontal plane directly

¹ *Forbes Neuro-ophthalmology*, 1914, p. 132.

operation for a bleeding otherwise uncontrollable and likely to prove fatal, or it may be undertaken for cases of recurrent hæmoptysis. I have treated a case of the latter class but adhesions have prevented the development of a really efficient pneumothorax. Nevertheless, a relative immunity from attacks has resulted from a mere relaxation of the diseased lung. Masenti, Borgogno, and Vergano found that total collapse was not needed, nor even a positive intra pleural pressure to secure an arrest of the hæmorrhage. A gas quantity between 250 and 1100 c.c. sufficed to attain this result in their five cases. It is best, however, to collapse the lung fully in these cases as in others whenever adhesions do not prevent it.

Contra indications

Disease of other organs, whether tubercular or not, may contra indicate the production of an artificial pneumo thorax

Lungs—The question of the better lung *qua* tuberculosis has already received consideration. Advanced emphysema and asthma are contra indications. Dyspnoea is in itself no contra indication, since it is in many cases toxic in origin and is relieved by the removal of auto-inoculation.

Circulatory organs and kidneys—Pneumothorax therapy may reduce the pulmonary vascular area in some cases at least, and thus put a strain on the right heart. In addition, the loss or reduction of intrathoracic suction tends to embarrass the venous circulation. The effect of these disabilities on circulatory organs and kidneys renders any serious disease of these organs a contra indication to pneumothorax therapy. On the other hand, it must be noted that certain cases of nephritis appear to be of tuberculo-toxic origin, and have been known to recover when auto inoculation was removed.

Laryngeal tuberculosis is no contra indication, unless very advanced, and then a doubtful one. Da Gradi has described three bad cases from Forlanini's clinic improved or healed. Slighter cases of laryngeal disease commonly improve, among 11 such cases mentioned by Zink all recovered except one very bad one, and that one improved very decidedly.

Intestinal tuberculosis is a contra indication, unless slight and consequently latent Brauer and Spengler, however, record two cases where intestinal disease led to symptoms, and where these disappeared under pneumothorax treatment

Diabetes is a complication which should make the physician very chary of recommending pneumothorax treatment

Conclusions

At the conclusion it may be stated shortly that pneumothorax treatment should be borne in mind in all cases where life is "threatened," but it must not be postponed till life is "in danger," for it is mostly then too late. The high function of pneumothorax therapy says Weiss, "is this—to restore lost cases to health", but the bad outlook must be recognised in good time if pneumothorax treatment is to succeed. A phthisis case may be to the initiated "lost," so far as ordinary methods of treatment are of avail, long before the end is in sight. It is at this stage, or even before, that the suitability of pneumothorax treatment must be decided upon if a clear other lung, absence of widespread adhesions and a re-expandable lung are to be with any likelihood attained. On the other hand it must be admitted that the advanced apparently unilateral, hilus tuberculosis cases are seldom met too late for this treatment and it is remarkable how often the pleura remains sufficiently unadherent to allow the production of an efficient pneumothorax over disease extending even from apex to base.

placed in Phillack Church as a memorial to the late Mr
George Vawdrey

BATH CITY COUNCIL AND THE MEDICAL OFFICER OF HEALTH—Owing to some friction between the Bath city council and the medical officer of health (Dr W H Symonds) the latter received an intimation to terminate his engagement on July 17th. Nine candidates were selected to appear before the sanitary committee last week of these five attended but subsequently withdrew their applications. After a long discussion the council decided to continue the existing arrangements until after the war and to withdraw the notice to Dr Symonds.

A CASE OF OBLIQUE HEMIANOPIA FROM WOUND OF OPTIC CHIASMA

BY PURVES STEWART, C.B., M.D. EDIN., F.R.C.P. LOND.,
COLONEL, & M.S. CONSULTING PHYSICIAN TO H.M. FORCES
AND
A.D. GRIFFITH, B.S. LOND., F.R.C.S. ENG.,
CAPTAIN R.A.M.C. (T) SPECIALIST IN OPHTHALMOLOGY

LESIONS of the chiasma without implication of the long tracts of the brain stem occur so infrequently that we deem the following case worthy of record

The patient, aged 24, was wounded on Jan 5th, 1916 and came under observation a week later. He had multiple shrapnel wounds of both upper limbs and of the right lower limb. In addition, one metallic fragment had entered through the right upper eyelid, destroying the right eye and lodging within the cranium, where radiography showed it to be about a quarter of an inch above and a quarter of an inch in front of the upper limit of the sella turcica. It had crossed the mesial plane and was lying half an inch to the left of the middle line. (See Figs 1 and 2.) When hit the patient immediately became unconscious and had a subsequent period of amnesia which lasted for several weeks throughout the attack of *septic meningitis* which followed. Two days after his injury, on board the hospital ship, it was noted that he was completely blind and that the pupil of the uninjured left eye was widely dilated and insensitive to light. The signs of severe meningitis rapidly increased with head ache, delirium, pyrexia, and head retraction. For the first ten days the patient seemed moribund, and minute observations on his eyes were impossible. He then began to improve and was more carefully examined on Jan 17th—i.e., 12 days after the injury. On this day the temperature, which since admission to hospital had been swinging between 100·8° and 103·4° F., was 101·8°. The pulse, which had varied from 88 to 103, was 95. The patient was now able to reply intelligently to questions although still at times mildly delirious. He complained of headache and cervical rigidity. The right eyeball was completely disorganised and suppurating. The left eye had no perception of light and its pupil was widely dilated and insensitive. The left optic disc and fundus were normal. In particular, there was no pallor of the disc and no suspicion of optic neuritis. The cranial nerves were otherwise normal. There was no sensory or motor paralysis of the face, trunk, or limbs. The knee jerks and ankle jerks were normal. The plantar reflexes were of the normal flexor type. Kernig's sign was well marked. The cerebrospinal fluid was opaque and milky, on standing it showed a thick deposit of pus. The meningitis gradually subsided during the next six weeks under treatment by arotropine internally, together with lumbar punctures on alternate days, the cerebrospinal fluid becoming normal.

On Jan 29th the right eye was excised. The globe was found to be full of blood clot. There was no obvious suppurative within the orbit. On Feb 4th—i.e. a month after the injury—it was observed that some vision had returned in the left eye in the nasal half of the field, so that the patient could distinguish hand movements close to the eye. On the 18th, when the meningitic symptoms had subsided and the cerebro spinal fluid had become almost clear, the hemianopia of the left field was confirmed. From the 24th onward the temperature remained steadily normal. On March 1st the lumbar punctures were discontinued.

On March 9th a more careful examination of the left eye was made. The optic disc was now diffusely pale and atrophic. The left pupil was widely dilated and showed a typical hemiopic reaction—i.e. when a pencil of light was thrown on the sensitive temporal half of the retina the pupil contracted whereas a similar pencil of light thrown on to the blind nasal half of the retina produced no reaction. The boundary between the blind and the seeing halves of the visual field was not vertical but oblique running through the 120 meridian (See Fig 3). On the 13th this obliquity of the hemianopic boundary was confirmed and a slight gain of vision was detected in the blind half of the field close to the fixation point (See Fig 4). On this day the vision was 1/60. By the 21st the vision had further improved to 5/60 and the visual field had also extended slightly more into the blind area both horizontally outwards and also in the 100 meridian downwards and inwards (see Fig 5) where the field had widened from the 8 circle to the 30 circle. Moreover there was now a little vision directly downwards and even a trace in the 75 meridian downwards and outwards. On the 23rd the pupillary reaction was no longer typically hemiopic, for now the pupil contracted to light thrown in from either side although more briskly to light from the seeing half of the visual field.

of the type of minor operation for which this form of anaesthesia is suitable

Table showing Length of Time taken in the Induction and Duration of Analgesia

Operation	Time taken in induction of analgesia.	Duration of analgesia.	Remarks
	Seconds	Min. sec.	
Multiple abscesses of neck incision and scraping	35	1 45	Complete analgesia
Removal of septic ingrowing toe-nail	40	2 0	
Circumcision	35	2 0	
Removal of septic ingrowing toe-nail	70	1 30	Shouted loudly no pain felt
Bubo incision and scraping	50	1 0	Complete analgesia.
Cutting off projecting portions of two phalanges with bone forceps	35	2 0	
Incision and scraping of axillary abscess	30	1 45	
Removal of two septic ingrowing toe-nails	45	2 30

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

TWO CASES OF THORACIC ANEURISM

By GEORGE J CONFORD, M D OXON

THE aortic arch is recognised as the most usual situation for the development of aneurysm, but it is somewhat remarkable to have found the same unusual cause of death in two successive post-mortem examinations, while death had taken place in an exactly similar manner in both cases.

CASE 1.—The patient was a sailor on a lightship aged 53 years, who had not complained of feeling ill until the moment of his fatal seizure. On the evening of Dec 26th, 1915, while at supper, he complained of sudden pain in the chest. His companions, seeing him turn very pale gave him some brandy and laid him on a seat, but he died almost immediately. A post mortem examination was made by the coroner's order and the following conditions were revealed. On opening the thorax the right pleural cavity was found full of clear serum and blood clot, there were no pleuritic adhesions and the lung was moderately collapsed but otherwise normal. The aorta was enlarged, the ascending part of the arch being converted into an irregular somewhat fusiform sac, more prominent posteriorly. Rupture had occurred at the posterior part of the sac near the origin of the innominate artery, and the mediastinal connective tissue was infiltrated with tough semi-organised blood clot, showing that oozing had been going on for some little time before the final catastrophe. There is no record of any symptoms during life, and no physical examination had been made, as the man never had occasion to consult a medical practitioner for years past.

CASE 2.—The patient was a soldier aged 33 years. So far as could be ascertained he had never suffered pain or inconvenience until five days before his death, and presumably there were no abnormal physical signs, as he had recently been examined before readmission to the army. On Feb 15th he complained of occasional difficulty in swallowing and had attended at the sick inspection room on this account. On the 20th he had been carrying a scuttle of coals and on returning, to his hut sat down on a bench and complained of sudden severe pain in his chest. He rolled over on to his back and the medical officer was summoned attended at once but found him dead. An order for a post mortem examination was given by the coroner and was made by me at the request of Dr W. R. Fitches the regimental medical officer. The right pleural cavity was found full of serum and blood clot as in the previous case but the aneurysm was situated at the lower part of the transverse portion of the aortic arch was irregularly sacculated in shape and the walls were very thin in parts. The interior of the sac was irregularly ridged and

perforation had occurred at the periphery of a small secondary projection jutting out from the posterior part of the main sac. Blood clot had infiltrated the mediastinal connective tissue, but was apparently quite recent and less tough than in the previous case. The aneurysm must have pressed upon the trachea and oesophagus, but presumably only lightly, as the dysphagia had only been occasional, and there had never been any dyspnoea. There was no alteration in the voice or other evidence of pressure on the recurrent laryngeal nerve. There was some evidence of syphilis in this case in the form of scars, almost certainly of specific origin. In neither case was there any marked degree of cardiac hypertrophy.

The similarity of these cases in their termination, the complete absence of premonitory symptoms in the first and the slight previous evidence of illness in the second, appeared of sufficient interest for me to place them on simultaneous record.

A CASE OF PERFORATED TYPHOID ULCER OPERATION, ACUTE OBSTRUCTION, OPERATION, RECOVERY

By F M NEILD, M B, B S LOND

A SUCCESSFUL case of operation for a perforated typhoid ulcer is scarcely worth recording, if it were not for the fact that acute obstruction took place nine days after, necessitating a further operation which was also successful.

The patient, a Portuguese half-caste boy aged 10, miserably thin, and looking half starved, was said to have been always delicate. He had a mild attack of typhoid lasting from Jan 25th to Feb 9th, 1915, Widal reaction positive. After the temperature had been normal for nine days he had a severe relapse and became extremely ill. In the early morning of March 9th he was seized with severe pain in the abdomen and vomited several times. The sister (nun), however, did not send for me, and I only saw him at 10 A.M. on my usual round. The temperature was 103° F., pulse 102, the abdomen was rigid and extremely tender, while the liver dullness was absent.

Operation took place at 12 30 P.M., about eight hours after the perforation took place. A small perforation was found about 1½ feet from the ileo-caecal valve, this was closed by a purse-string suture. There were no signs of peritonitis except for a few shreds of lymph near the perforation. A quantity of brown fluid was removed from the pelvis by dry sponging. The boy's condition was very poor, so the wound was closed with through-and-through silkworm gut sutures, a rubber drainage-tube being left in the lower end of the wound leading down into the pelvis. The same evening he was very collapsed, temperature 96°, pulse 140 and very feeble, but he rallied with subcutaneous injections of saline and camphorated oil. There was great difficulty in getting the bowels to move, and for the first two days no flatus was passed, and then only after the passage of a long rectal tube. The drainage-tube was removed on the third day. The bowels moved naturally on the fourth day and then every day once or twice until March 18th. The stitches were removed on the 16th, owing to tension there was a good deal of sloughing and pus was oozing from the stitch holes.

When I saw him on the morning of the 18th he seemed to be in great pain and had been vomiting continuously for several hours. Temperature 97°, pulse 140 very small and feeble. The abdomen was distended but not markedly tender. An enema produced no result and no flatus was passed after the passage of a rectal tube. Operation was decided on but a very gloomy prognosis was given especially on account of the condition of the external wound. The anaesthetic was ether, given by the open method. The old wound was opened up. The bulk of the small intestine was distended, but in the right iliac fossa a collapsed portion was seen a band of omentum passing down towards this. On pulling up the bowel the obstruction was released and gas at once passed into the collapsed intestine. The exact mechanism of the obstruction could not be seen, but it occurred at the site of the perforation. The bowel wall here was denuded of peritoneum to a small extent. This denuded area was closed over with Lambert sutures. The abdominal wound was completely closed without drainage by through and through stitches. The operation only lasted 15 minutes from start to finish. His condition immediately afterwards was much better than before and no further vomiting took place. Flatus was soon passed and the bowels were moved with castor oil on the second day. The day following operation the patient was clamouring for food. There was scarcely any rise of temperature after the operation. The stitches were removed on the tenth day and recovery was uninterrupted.

Shanghai

outwards from the fixation point. These latter fibres, from their central position in nerve and chiasma, would be well protected from injury. In addition, a number of fibres destined for the left optic tract are also implicated—viz., those corresponding to the lower and mesial sector of the right half of the visual field.

EARLY ETHER ANALGESIA

By D P D WILKIE, M D, M CH EDIN, F R C S EDIN,

ACTING STAFF SURGEON R N V R.

THE question of the choice of anæsthetic for minor operations is one of perennial interest, but never more so than in war time, when, in the Services, minor operations acquire a new and peculiar importance. For the class of case for which a local anæsthetic is unsuitable—e.g., in dealing with inflamed tissues, and where a very brief though painful operation is necessary—such anæsthetics as nitrous oxide and ethyl chloride are commonly employed. In hospitals the apparatus required for the administration of these anæsthetics will practically always be available. Such is not the case, however, on active service on board ship or in the field, where the medical officer must, like the general practitioner, use methods which do not involve any cumbersome apparatus. For him it remains to decide between chloroform and ether, with the disadvantages associated with full surgical anæsthesia in the case of both these drugs.

For the past few years I have used ether as the anæsthetic in such cases, but have taken advantage of the transient stage of analgesia which supervenes when ether is supplied abundantly, long before the patient could be said to be 'under' in the ordinary sense of the word. I have found this method of anæsthesia exceedingly useful, as it is time saving and perfectly free from danger.

In the text-books on anæsthetics which I have consulted I can find no reference to this method of employing ether.

FIG 1

Materials required for inducing early ether analgesia: the Schimmelbusch mask, a measure containing 3 drachms of ether, and a hand towel folded double.

for minor operations. The only reference I have found to this early stage of analgesia under ether is in Buxton's book on anæsthetics, where in describing the 'second stage' of anæsthesia under ether the author states that "semi-anæsthesia exists and pain even if slightly felt is seldom remembered as pain upon awakening." He points out that this is probably the degree of anæsthesia of which Plan wrote when he described patients who moved freely and appeared conscious but were nevertheless oblivious to the surgeon's knife. During the war whilst serving in the navy, I have been able to give this method a thorough test and have endeavoured to standardise its use and now feel in a position to recommend it with confidence to the profession.

In making practical use of this transient phase of analgesia certain conditions are essential for uniform success. The ether vapour must be given concentrated from the start and the patient must inspire regularly and fairly deeply. Neurotic and unwilling patients are therefore unsuitable.

The only apparatus required is a Schimmelbusch mask (preferably the modified form described below) also a towel and a receptacle which will hold 3 drachms of ether. The

part to be operated upon having been cleansed and the operator being ready with the necessary instruments to hand, an ordinary hand towel folded double is laid across the patient's neck and chest, the mask is placed over his nose and mouth, and the ether (3 drachms) is measured out in readiness to pour on to the mask. (Fig 1.) The patient is warned to breathe quietly and deeply as soon as the ether is applied to the mask. At a signal from the surgeon that all is ready the whole quantity of ether (3 drachms) is poured over the mask and the folded towel brought over the face and mask and kept closely applied. (Fig 2.) It will be found that in from 30 to 50 seconds provided that the patient breathes regularly, the stage of analgesia has set in and will last from 50 seconds to 3 minutes, the usual duration being slightly less than 2 minutes. During this period the patient will usually remain quiet, even though inflamed parts are being forcibly dealt with as e.g. in removing a septic ingrowing toe nail, occasionally he

FIG 2

The analgesia induced: the 3 drachms of ether have been poured over the mask, the folded towel brought over and kept closely applied.

will shout, though remaining quite still. This may be disregarded, as on recovering a few moments later he will state that he has felt no pain. Within one minute of completing the operation the patient is usually awake and is always in the best of humour, the ether having acted as a pleasant stimulant. He is able to walk out of the theatre and to take a meal shortly afterwards. There appear to be no unpleasant after effects.

In administering the ether with the ordinary Schimmelbusch mask, it was found on applying the towel over the face and mask that some of the ether was absorbed by the towel and thus partly lost. The modified mask which has two extra folding supports to keep the towel off the lint which is soaked with ether, is a distinct advantage. (Fig 3.) It is supplied by Messrs Allen and Hanbury, Wigmore street, London, W., and will be found useful for the administration

FIG 3

A modified Schimmelbusch mask with two extra folding supports to keep the towel off the ether-soaked lint.

of ether by the 'open' method when full surgical anæsthesia is desired a piece of Gamgee tissue with a central hole being laid over the outer hoop, thereby preventing the too rapid evaporation of the ether without blocking up and wasting the drug.

The following short list of cases given in tabular form showing the length of time used in the induction of analgesia and the duration of analgesia gives a good idea

of the type of minor operation for which this form of anaesthesia is suitable

Table showing Length of Time taken in the Induction and Duration of Analgesia

Operation	Time taken in Induction of analgesia.		Duration of analgesia.	Remarks
	Seconds	Mn. sec.		
Multiple abscesses of neck incision and scraping	35	1 45	Complete analgesia.	
Removal of septic ingrowing toe-nail	40	2 0		
Circumcision	35	2 0	Shouted loudly, no pain felt.	Complete analgesia.
Removal of septic ingrowing toe-nail	70	1 30		
Bubo incision and scraping	50	1 0	Complete analgesia.	
Cutting off projecting portions of two phalanges with bone forceps	35	2 0		
Incision and scraping of axillary abscess	30	1 45	Complete analgesia.	
Removal of two septic ingrowing toe-nails.	45	2 30

TWO CASES OF THORACIC ANEURISM

By GEORGE J CONFORD, M.D OXON

THE aortic arch is recognised as the most usual situation for the development of aneurysm, but it is somewhat remarkable to have found the same unusual cause of death in two successive post mortem examinations, while death had taken place in an exactly similar manner in both cases.

CASE 1.—The patient was a sailor on a lightship aged 53 years, who had not complained of feeling ill until the moment of his fatal seizure. On the evening of Dec 26th, 1915 while at supper he complained of sudden pain in the chest. His companions, seeing him turn very pale gave him some brandy and laid him on a seat, but he died almost immediately. A post mortem examination was made by the coroner's order and the following conditions were revealed. On opening the thorax the right pleural cavity was found full of clear serum and blood clot, there were no pleuritic adhesions and the lung was moderately collapsed but otherwise normal. The aorta was enlarged, the ascending part of the arch being converted into an irregular somewhat fusiform sac more prominent posteriorly. Rupture had occurred at the posterior part of the sac near the origin of the innominate artery and the mediastinal connective tissue was infiltrated with tough semi-organised blood clot showing that oozing had been going on for some little time before the final catastrophe. There is no record of any symptoms during life, and no physical examination had been made, as the man never had occasion to consult a medical practitioner for years past.

CASE 2.—The patient was a soldier aged 35 years. So far as could be ascertained he had never suffered pain or inconvenience until five days before his death, and presumably there were no abnormal physical signs, as he had recently been examined before readmission to the army. On Feb 15th he complained of occasional difficulty in swallowing and had at ended at the sick inspection room on this account. On the 20th he had been carrying a scuttle of coals and on returning to his hut sat down on a bench and complained of sudden severe pain in his chest. He rolled over on to his back and the medical officer was summoned attended at once but found him dead. An order for a post mortem examination was given by the coroner and was made by me at the request of Dr W. R. Fitch, the regimental medical officer. The right pleural cavity was found full of serum and blood clot as in the previous case, but the aneurysm was situated at the lower part of the transverse portion of the aortic arch was here almost coccalated in shape and the walls were very thin and brittle. The interior of the sac was irregularly ridged and

perforation had occurred at the periphery of a small secondary projection jutting out from the posterior part of the main sac. Blood clot had infiltrated the mediastinal connective tissue, but was apparently quite recent and less tough than in the previous case. The aneurysm must have pressed upon the trachea and oesophagus, but presumably only lightly, as the dysphagia had only been occasional, and there had never been any dyspnoea. There was no alteration in the voice or other evidence of pressure on the recurrent laryngeal nerve. There was some evidence of syphilis in this case in the form of scars almost certainly of specific origin. In neither case was there any marked degree of cardiac hypertrophy.

The similarity of these cases in their termination, the complete absence of premonitory symptoms in the first and the slight previous evidence of illness in the second, appeared of sufficient interest for me to place them on simultaneous record.

A CASE OF PERFORATED TYPHOID ULCER OPERATION, ACUTE OBSTRUCTION, OPERATION, RECOVERY

By F M NEILD, M.B, B.S LOND

A SUCCESSFUL case of operation for a perforated typhoid ulcer is scarcely worth recording, if it were not for the fact that acute obstruction took place nine days after, necessitating a further operation which was also successful.

The patient, a Portuguese half-caste boy aged 10, miserably thin, and looking half starved, was said to have been always delicate. He had a mild attack of typhoid lasting from Jan 25th to Feb 9th, 1915. Vidal reaction positive. After the temperature had been normal for nine days he had a severe relapse and became extremely ill. In the early morning of March 9th he was seized with severe pain in the abdomen and vomited several times. The sister (nun), however, did not send for me, and I only saw him at 10 A.M. on my usual round. The temperature was 103° F., pulse 102, the abdomen was rigid and extremely tender, while the liver dullness was absent.

Operation took place at 12.30 P.M., about eight hours after the perforation took place. A small perforation was found about 1½ feet from the ileo-caecal valve, this was closed by a purse string suture. There were no signs of peritonitis except for a few shreds of lymph near the perforation. A quantity of brown fluid was removed from the pelvis by dry sponging. The boy's condition was very poor, so the wound was closed with through and through silk worm gut sutures, a rubber drainage tube being left in the lower end of the wound leading down into the pelvis. The same evening he was very collapsed, temperature 96°, pulse 140 and very feeble, but he rallied with subcutaneous injections of saline and camphorated oil. There was great difficulty in getting the bowels to move, and for the first two days no flatus was passed, and then only after the passage of a long rectal tube. The drainage tube was removed on the third day. The bowels moved naturally on the fourth day and then every day once or twice until March 18th. The stitches were removed on the 16th, owing to tension there was a good deal of sloughing and pus was oozing from the stitch holes.

When I saw him on the morning of the 18th he seemed to be in great pain and had been vomiting continuously for several hours. Temperature 97°, pulse 140 very small and feeble. The abdomen was distended, but not markedly tender. An enema produced no result and no flatus was passed after the passage of a rectal tube. Operation was decided on, but a very gloomy prognosis was given, especially on account of the condition of the external wound. The anaesthetic was ether, given by the open method. The old wound was opened up. The bulk of the small intestine was distended, but in the right iliac fossa a collapsed portion was seen a band of omentum passing down towards this. On pulling up the bowel the obstruction was released, and gas at once passed into the collapsed intestine. The exact mechanism of the obstruction could not be seen, but it occurred at the site of the perforation. The bowel wall here was denuded of peritoneum to a small extent. This denuded area was closed over with a Lembert suture. The abdominal wound was completely closed without drainage by through and through stitches. The operation only lasted 15 minutes from start to finish before and no further vomiting took place. Flatus was soon passed and the bowels were moved with castor oil on the second day. The day following operation the patient was clamouring for food. There was scarcely any rise of temperature after the operation. The stitches were removed on the tenth day and recovery was uninterrupted.

Reviews and Notices of Books.

Operative Midwifery.

By J M MUNRO KERR, M D, C M Glasg, Professor of Obstetrics and Gynecology, Glasgow University, Obstetric Physician to the Glasgow Maternity Hospital. Third edition. With 308 plates and figures in the text. London: Baillière, Tindall, and Cox. 1916. Pp xvi + 725. Price 25s net.

THE appearance of the third edition of Professor Munro Kerr's book on "Operative Midwifery" has been delayed by the war, and five years have elapsed since the second edition was published. A good many alterations have been made in the text. Thus the author's latest results in the treatment of contracted pelvis, the application of forceps, the performance of pubiotomy, Cæsarean section, and other operative procedures have been added and increase the value of the work very considerably. Five years' further experience has not led to any marked modification of the views held by the author on the many obstetric problems which he discusses, and the result is a work embodying an exceptionally large experience of difficult cases of labour and containing a great deal of sound information. It is interesting to note that the author is more and more convinced of the safety for both the mother and the child of spontaneous delivery in cases of contracted pelvis, and his experience coincides with ours when he says that it is very difficult to convince other people of this fact. Professor Munro Kerr's teaching as to the use of forceps in contracted pelvis is very good. By not applying the instrument until the head has been given adequate time to mould, by not applying it to the head above the brim or when there is a posterior parietal presentation, and by not continuing attempts at forceps delivery after two failures with a moderate degree of traction and the patient in Walcher's position, his results have very much improved.

The chapter dealing with pubiotomy contains a well-balanced summary of the reasons for and against this operation. That the author is not an undue advocate of the procedure is shown by the fact that while Cæsarean section has been performed 120 times in the Glasgow Maternity Hospital during the years 1900 to 1913, pubiotomy has only been practised on eight patients. The interesting suggestion made by Rotter, of Budapest, in 1912 is alluded to. He advised resection of the promontory of the sacrum in a contracted pelvis so as to produce permanent enlargement of the brim, and at the time he published his paper had practised the operation on nine patients. The statistics furnished by the author of the results of the induction of premature labour for contracted pelvis show that the foetal mortality is not unduly high when the conjugata vera measures from 34-3½ inches, and that with more careful selection of the cases the mortality should be still further lowered, as has happened in these series of cases. On the whole, however, Professor Munro Kerr cannot be called an enthusiastic advocate of the operation, but his opinion on the subject is the more valuable since his experience of the treatment of contracted pelvis is large and his book shows that he does not condemn any method of treatment without good reason.

We can confidently recommend this third edition as a most trustworthy guide for the student and the practitioner.

Text book on Nervous Diseases

By Professor H CURSCHMANN, of Mainz, and 14 other Contributors (German and Austrian). Authorised English edition by CHARLES W BURR, B S, M D, Professor of Mental Diseases in the University of Pennsylvania. In two volumes. With 156 text illustrations. Philadelphia: P Blakiston's Son and Co. 1915. Pp 1132. Price \$12 net the two volumes.

Professor C W Burr has edited an English version of a recent text-book of nervous diseases compiled by various leading German and Austrian neurologists with Professor Curschmann of Mainz, as its general editor. Neurology of to-day stands in intimate relation with internal medicine in general and with psychiatry in particular but it is also linked to ophthalmology, otology, dermatology, bacteriology and ærology and surgery. As specialism increases with the sum of human knowledge there appears

to be a widely disseminated feeling that the text-book of to-day should be a compilation, a symposium, made up of individual contributions from specialists in various adjacent fields of study. There are advantages and disadvantages alike in this method. Professor Curschmann declares in his preface that he is not blindly following the fashion of the coöperative method in text book production, but that the peculiarity of neurology forces him to include the above allied sciences, in so far as they bear on neurology, in his presentation of the subject for the non-specialist. However concise and compact the individual contributions are, a text book of this description is apt to suffer from certain inequalities and tendencies to overlapping, and the different points of view are sometimes rather confusing to the beginner.

Taken as a whole, the volumes under review contain a thoroughly up-to-date and instructive presentation of the science of neurology. Some of the individual articles are excellent alike in matter and in style, others are valuable because they supply information not often so collected. Professor Liepmann's chapter on the normal and pathological physiology of the brain, for instance, is a particularly good *multum in parvo*. On the other hand, the article on "vasomotor and trophic diseases" is a curious conglomerate, for it includes certain diseases of the endocrine glands and omits others in an unsatisfactory fashion. The editor has evidently been embarrassed by the question of what constitutes a nervous disease and what does not. Exophthalmic goitre, myxœdema, and acromegaly are included, while the suprarenal gland is apparently taboo.

The editor of the English edition has added a chapter on the diagnosis and treatment of neurasthenia, psychasthenia, hysterics, and borderline mental states, written from a different point of view from that of the original contributors to the same subjects. The translation runs smoothly enough, but it shows evidence of different hands, and some parts—e.g., the chapter on "general diagnostics of nervous diseases"—are not up to the level of translation of the rest of the book.

Veterinary Therapeutics. A Guide to the Treatment of Disease in the Domestic Animals

By E WALLIS HOARE, F R C V S, Lecturer on Veterinary Hygiene, University College, Cork. Third edition. London: Baillière, Tindall, and Cox. 1916. Pp 943. Price 18s net.

THIS well known text-book has been revised and modernised by the author. As in previous editions the subject matter is divided into three main parts. The first section contains a valuable account of the care, management, and nursing of sick animals. The difficulties with which practising veterinary surgeons have to deal are legion and often imperfectly understood by owners and attendants, who may obtain from these pages an intelligent understanding of the carrying out of hygienic and dietetic measures, among ailing animal patients. In the care, management, and nursing of cattle, dogs, cats, and birds, stress is laid on the fact that drugs only aid the power of recovery, they do not ensure it, hence routine and repeated dragging is condemned. Other matters discussed in this section are the diagnosis and general symptoms of disease, the actions and uses of drugs, and the administration of medicines. Part II deals with materia medica, avoiding elaborate detail of manufacture, and giving the knowledge necessary to the student and practitioner for the application of the remedies to disease. Where the employment of one salt of an element is more advantageous than another the fact is noted and the reason given. The list of preparations is very complete, comprising both modern as well as older and well tried remedies. A chapter is devoted to the various vaccines and serums used in veterinary practice. Part III is taken up with the special therapeutics of various diseases, and includes chapters on the care, management, and nursing of sick sheep and pigs. A feature of the book is the account given of the actions of drugs as obtained from animal experiment.

In the production of his book the author has had the coöperation of Messrs H Bock, F R C V S, G Marshall, F R C V S, W M Scott, F R C V S, and H Gray, F R C V S. It makes a distinct advance on any hitherto published in this special sphere, is well arranged and carefully indexed.

LIBRARY TABLE

A New Treatment for Gonorrhoea By CHARLES RUSS, M B Lond London H K Lewis and Co Pp 38 Price 3s net.—In this small work the author describes a system of treatment applied by him in recent years to the cure of gonorrhoea. It is founded on experimental studies of the effects resulting from the passage of a constant electric current on bacteria immersed in fluid. It is claimed that the current causes the bacteria to accumulate gradually at the positive electrode and to bring about the death of the organisms in a short space of time. The method consists in passing a platinised catheter down to the compressor urethra. This catheter has numerous perforations and is furnished with a stylet of platinum wire which just enters the meatus. A lint covered pad with a metallic core, soaked in warm saline is placed on the perineum and a 2 per cent solution of sodium iodide is injected into the catheter. The pad is then connected with the negative and the stylet within the catheter to the positive pole of the battery. At the end of each treatment the perforations in the catheter are filled with masses of mucus, which on microscopic examination are found to be swarming with killed gonococci. The author claims that in this way a simple and limited attack of gonorrhoea can be cured in from 10 to 20 administrations and that complications are extremely rare. This treatment has had no wide application at present, and experience alone can decide as to its efficacy. It has not been found very successful for suppurative in general, and it would seem improbable that the electro-chemical reactions could penetrate into all the lacunae and glands of the urethra without causing damage of tissues.

Pye's Surgical Handicraft. A Manual of Surgical Manipulations. Minor Surgery, and Other Matters connected with the Work of House Surgeons and Surgical Dressers Edited and largely rewritten by W H OLATTON GREENE, B A., M B., B C Camb, F R C S Eng, Surgeon to St Mary's Hospital. Seventh edition, fully revised. Bristol John Wright and Sons, Limited, London Simpkin, Marshall, Hamilton, Kent, and Co, Limited 1916 Pp 614 Price 15s net.—A new edition of this well known work is especially timely just now when the house surgeons and surgical dressers, for whom it is primarily intended, are working with less help from senior and experienced officers than was the case in more fortunate times. The book remains a safe guide for them and a useful work of reference also for the practitioner whose memory may now and then fail him on a point of minor surgery or the application of a contrivance. Some sections have been revised and some rewritten, and the book has been made more complete by the inclusion of a useful and well illustrated chapter on the use of X rays from the pen of Dr Harrison Orton. In its newest form "Pye" will continue to enjoy popularity.

The Drink Problem of To-day in its Medico-Psychological Aspects Edited by T N KELYNACK M D Vict., Honorary Secretary of the Society for the Study of Inebriety, Editor of the *British Journal of Inebriety* London Methuen and Co 1916 Pp 316 Price 7s 6d net.—This book is a revised and enlarged edition of "The Drink Problem" a collection of essays on the various biological and sociological aspects of alcoholism which was published in "Methuen's New Library of Medicine" in 1907. In the production of the present volume the editor, Dr T N Kelynnack, has had the assistance of most of the experts who collaborated with him in the earlier publication, and he has also secured several additional contributions of value from other writers qualified by their special knowledge and experience to speak with authority on particular aspects of this complex question. Amongst these new chapters may be indicated an admirable essay on Alcohol and War, by Sir A. Pearce Gould, a vigorous if somewhat controversial discussion of the principles of temperance legislation by Sir T P Whittaker, a clear and concise review of the medico legal relations of alcoholism, by Sir W J Collins, and a very interesting survey of the history of opinion with reference to the alcohol question by Mr J Turner Rae. By the inclusion of this fresh matter, and as a result of the very extensive revision of the older chapters most of which have been practically rewritten the book has acquired many of the characters of a new work. With such a multiplicity of contributors—each of the 15 chapters is from a different hand—it is obviously difficult to maintain a unity of outlook and a uniformly high level of quality, but on the whole the work is very little open to criticism

with respect to either of these points. And it also shows singularly little evidence of the defects of omission and overlapping which are so frequently incidental to the method of collaboration. Most of the contributors hold strong temperance views, and this fact has in a few instances led to a slightly over emphatic presentation of the possible dangers of alcohol. But such lapses are very rare and are confined to a few chapters. The work as a whole is written in an eminently fair and temperate spirit, and with a regard for the scientific canons of evidence which is not always a conspicuous feature of the literature of the subject. The circumstances of the moment have brought the problem of alcoholism into special prominence, and it is a matter of urgent importance that public opinion should be educated to appreciate the fundamental factors of that problem and to understand the principles of which account must be taken in efforts to arrive at its solution. This volume is well fitted to assist in such an educational process, and we trust that it will be as widely read as its merits deserve. It should be added that the value of the work has been very much enhanced by an extremely full and admirably arranged index.

Practical Cystoscopy and the Diagnosis of Surgical Diseases of the Kidney and Urinary Bladder By PAUL M PILCHER, A.M., M.D., Consulting Surgeon to the Eastern Long Island Hospital. Second edition, thoroughly revised. With 299 illustrations. 29 being in colours. London and Philadelphia W B Saunders Company Pp 398 Price 25s net.—Only a few years have elapsed since the student of urinary surgery was in a position to complain of the want of text-books dealing with the cystoscopic examination of the bladder. That reproach to surgical authorship has certainly been removed, for now there are several works dealing with this subject and one of the best of these is the volume before us. In his second edition Dr Pilcher has maintained the high level which he reached in the first. There are many alterations, but the main change has been in the recognition of the great importance of pyelography, and to this method of diagnosis a new section has been devoted, the technique is clearly described and the value of the indications afforded by cystoscopy is discussed in an unbiased manner. Several excellent "pyelograms" are also given. Altogether we can commend this text-book.

Emergency Surgery By JOHN W SLUSS, A.M., M.D. Associate Professor of Surgery, Indiana University School of Medicine, ex Superintendent of the Indianapolis City Hospital. Third edition, revised and enlarged. With 685 illustrations, some of which are printed in colours. London William Heinemann (Rebman Limited) Pp 832 Price 17s 6d net.—This edition maintains the excellence of the earlier issues and the additions made by the author have brought it up to the level of the recent advances of surgery. Especial attention has been devoted to the subject of fractures, and the author has entirely rewritten the chapter on military surgery to make it accord with the lessons learned in the present war. The book has been written for the benefit of the general practitioner, and though many operations are described in it which the practitioner would not undertake in ordinary circumstances, yet in emergencies it is difficult to limit what he may have to do. It is wise, therefore, to include too much rather than to omit anything which might be needed. The book is well and clearly written, many of the illustrations are original, and those which have been borrowed from other sources have been chosen wisely.

JOURNALS

Physiological Abstracts Vol I Nos. 1-4 London H K Lewis and Co. Published monthly. Annual subscription 25s, post free.—Earlier in the year we announced the impending publication of a new journal with the above title which is a venture of the Physiological Society of Great Britain and Ireland with the co-operation of the American Physiological Society and of other societies and savants in eight countries. Four monthly numbers have now appeared, and the latest of which for July contains 224 separate abstracts, and we take this opportunity of congratulating the editor (Professor W D Halliburton) and his staff of abstractors on it to all those who are interested in the advances being made in physiology and its sister sciences. The war has considerably curtailed research work in European countries, and we note that America just now takes the lead in the number of papers published. Representative physiologists of allied and

There are many alterations, but the main change has been in the recognition of the great importance of pyelography, and to this method of diagnosis a new section has been devoted, the technique is clearly described and the value of the indications afforded by cystoscopy is discussed in an unbiased manner. Several excellent "pyelograms" are also given. Altogether we can commend this textbook.

Emergency Surgery. By JOHN W. SLUSS, A.M., M.D., Associate Professor of Surgery, Indiana University School of Medicine, ex-Superintendent of the Indianapolis City Hospital. Third edition, revised and enlarged. With 685 illustrations, some of which are printed in colours. London: William Heinemann (Rebman Limited). Pp. 632. Price 17s. 6d. net.—This edition maintains the excellence of the earlier issues and the additions made by the author have brought it up to the level of the recent advances of surgery. Especial attention has been devoted to the subject of fractures and the author has entirely rewritten the chapter on military surgery to make it accord with the lessons learned in the present war. The book has been written for the benefit of the general practitioner and though many operations are described in it which the practitioner would not undertake in ordinary circumstances, yet in emergencies it is difficult to limit what he may have to do. It is wise, therefore, to include too much rather than to omit anything which might be needed. The book is well and clearly written, many of the illustrations are original, and those which have been borrowed from other sources have been chosen wisely.

JOURNALS

Physiological Abstracts. Vol. I. Nos. 1-4. London: H. K. Lewis and Co. Published monthly. Annual subscription 25s. post free.—Earlier in the year we announced the impending publication of a new journal with the above title, which is a venture of the Physiological Society of Great Britain and Ireland with the co-operation of the American Physiological Society and of other societies and savants in eight countries. Four monthly numbers have now appeared, and we take this opportunity of congratulating the editor (Professor W. D. Halliburton) and his staff of abstractors on it to all those who are interested in the advances being made in physiology and its sister sciences. The war has considerably curtailed research work in European countries, and we note that America just now takes the lead in the number of papers published. Representative physiologists of allied and

neutral countries are collaborating in this work of replacing similar periodicals which have hitherto been published in Germany, and we note with pleasure how prompt has been the work of the abstractors, in this feature the new publication compares very favourably with its German predecessors. We anticipate a brilliant future for *Physiological Abstracts* and wish it every success.

New Inventions

A NEW MECHANICAL STAGE

In addition to the usual advantages of a mechanical stage, the invention here illustrated is easily fixed to, and unfixed from, any microscope. This is effected very simply. To the right on the under side of the machine is a strong

curved leaf spring, attached at its proximal end to a firm crossbar, on the left at a convenient distance are pivoted

two spring fingers. The machine is slipped over the anterior edge of the stage, the curved spring firmly presses the right edge of the stage, while the two spring fingers grip its left edge and under surface. This construction is sufficient to hold the machine immovably upon the stage, and is adapted to engage stages of different widths within the limits of stage sizes usually employed with microscopes.

The Medical Supply Association, 167 185, Gray's Inn road, W.C., are the manufacturers.

A MONTHLY RECORD OF ATMOSPHERIC POLLUTION

THE returns in some instances have not been forthcoming, a number of stations having discontinued making observations owing to the reduction of staff. It is hoped that the omissions due to this cause will be made good when normal times return. The personnel of public health authorities concerned in the supervision of these examinations and of the analytical work involved remains the same as published in previous tables.

COMMITTEE FOR THE INVESTIGATION OF ATMOSPHERIC POLLUTION

Summary of Reports for the Months ending February and March, 1916

The Food of the Prisoners at Ruhleben Camp

FURTHER correspondence between Sir EDWARD GREY and the American Ambassador respecting the conditions of diet and nutrition in the internment camp at Ruhleben has been published, and contains two reports by Dr A E TAYLOR to the American Embassy at Berlin. In the first of these, dated May 24th, Dr TAYLOR states that since his last report a sharp reduction has been made in the amount of foodstuff allotted to the camp, the civilian prisoners at Ruhleben only receiving half the allowance of potatoes and little more than a third of the protein foods allotted to military prisoners of war in other camps. In the second report, dated June 14th, a more detailed analysis of the diet is given. The ration established for military prisoners of war in Germany in the month of June contained 2700 calories a day, made up of 80 grammes of protein, 29 of fat and 500 of carbohydrate. This, though not plentiful, is an adequate diet as regards its calorie value for average men not doing much muscular work. It contains about a hundred calories more than the peace ration of the German soldier. The proportion of protein is low, but is just enough to maintain nitrogenous equilibrium with a sedentary life. The proportion of fat is very low, indeed, no fat is given except that which is inseparable from the articles of food supplied. For growing children such a low fat ration would be harmful, but it need not endanger nutrition in adults provided the requisite food value is made up by other food stuffs, in this case carbohydrate. The diet for military prisoners of war, therefore, though poverty stricken as regards its protein and fat, is theoretically enough to maintain nutrition if it is supplied in a form that can be digested and assimilated, a matter upon which we have ground for doubt.

The diet supplied to the civilian prisoners at Ruhleben admits of no such defence. It contained originally only 1580 calories a head, more than a thousand calories less than that for military prisoners. This is wholly insufficient. Its heat value 23 calories per kilogramme for a man of 11 stone, is barely enough to keep him nourished, even if it were in a most assimilable form, such as milk and eggs and he were resting entirely in bed. With the conditions of camp life and German camp food it would be starvation. As, however, many prisoners ate little or none of the camp ration having food supplies of their own, more was left for the others, so that the actual calorie

value received by each man living on the camp food was brought up to a sufficient figure—namely, 2725 calories, containing 98 grammes of protein. But with the further recent reductions this compensation fails, for in the week May 4th–11th only 1220 calories a day were supplied, with 39 grammes of protein and 6 of fat. Such a diet, both as regards its heat value and its constituent foodstuffs, is wholly inadequate. If doubled it would be barely sufficient. Even when the food not eaten by more fortunate prisoners is added, it appears that a civilian in Ruhleben living on the camp food—and there were 2070 such—could only get 1930 calories a day, with 55 grammes of protein and 10 of fat. This might prevent starvation if it were in a suitable form, but it is not. Fat, sugar, and vegetables are not supplied. Further deductions must, therefore, be made for food which is unpalatable or not digestible. It is, indeed, too clear that a large number of the interned civilians are not getting enough to eat.

In the following table the Ruhleben diets are compared with ordinary standards of living—

	Calories	Protein	Fat	Carbo- hydrate
English labourer	3655	184	71	570
German farm labourer (Ranke)	4696	143	103	783
Standard diet for a man of moderate activity	2820	100	100	360
Military prisoners of war in Germany	2700	80	29	500
Ruhleben diet before reduction	1580	59	12	308
Diet actually taken when increased by food left by other prisoners receiving supplies	2725	98	24	523
Ruhleben diet since reduction	1220	39	6	255
Reduced diet when increased by food left by others	1930	55	10	410

If anyone has lulled himself with the reflection that the most urgent needs of the interned were met by parcels from home he will learn from Dr TAYLOR'S report that many of the agencies sending food into Ruhleben, of which 23 are scheduled, are unsatisfactory. Some of them are doing very little, some are irregular, and others are not properly organised. More care is needed in the selection and packing of food. Parcels are sometimes as long as five weeks on the way, during which time much of the food has gone bad, especially the bread. The quality of the bread ordered from Switzerland has also deteriorated. Bread will keep if properly made and packed, for it is reported that loaves from the Army and Navy Stores and from John Barker and Co arrive in good condition. It is to be hoped that in future all agencies sending food will work with the Prisoners of War Help Committee which has been set up by our Government to coördinate their efforts. Pending the result of protests and negotiations through the American Embassy, Sir EDWARD GREY is endeavouring to arrange for a supply of food to be sent to the captain of the camp, pointing out at the same time that His Majesty's Government in no way admit their liability to feed prisoners in Germany, which is the recognised duty of the captor Government.

The Factory Department in Time of War

THE annual report of the Chief Inspector of Factories and Workshops for the year 1915, issued last week, is of special interest since it deals with the circumstances which have arisen in connexion with the war. The document bears eloquent tribute to the wonderful spirit which the industrial population of the nation has shown in our hour of need. In spite of the bitter strain thrown upon the workers there is no evidence of any marked increase in the sickness rates, and the inspectors are able to show that there has been an almost entire absence of complaints that operatives are being taxed beyond their strength. There can be little doubt, as Sir ARTHUR WHITELEGGE observes, that the high wages, and the better food which workers have been able to enjoy in consequence have done much to counteract the stress of long hours and to bring about this result. Cases of fatigue, as might well be expected, have occurred, but by adopting a policy of temporary relief in such cases there is usually full recovery of energy again. They occur commonly where overtime has been continued for long and uninterrupted periods. In certain cotton mills, however, periodical medical examination of the workers has been made a condition of a continuance of overtime, and power is given to the examining surgeon, by consent, to suspend, either wholly or for a period, anyone showing signs of fatigue. This has proved to be a satisfactory safeguard, and workers thus suspended are reported to recuperate rapidly so as to be quite fit to resume their task again.

It will be understood that in order to deal with this vast call upon the resources, energies, and materials of the country an extension of the powers exercised in the Factory Acts had in many instances to be made. The work in war time is controlled by a General Order from the Home Office, providing rules in regard to overtime and work involving day and night shifts. This Order appears to have satisfied the needs in most cases, but for others special Orders have been required, and more particularly for the large munition firms, in some of which the hours have remained in advance of those permitted by the General Order. Sunday labour, it is reported, has been found to be more and more unsatisfactory, and there appear to be economic as well as health reasons for excluding this from the category of a work day, employers having accepted the recommendations of the Health of Munition Workers Committee to this effect. The plan advised was to arrange the work so that there should not be more than 12 shifts per fortnight or 24 where double shifts are worked and where three 8 hour shifts are worked not less than two should be omitted on Sunday. It is preferable to work a moderate amount of overtime during the week allowing a break on Sunday, rather than work continuously from day to day, and it is still more strongly the view of the Chief Inspector that where overtime is worked in the week Sunday labour is not desirable.

One of the most striking facts disclosed in this report is the remarkable adaptability that women have shown in taking up the duties which hitherto have been assigned to men. Sir ARTHUR WHITELEGGE sets out no less than 28 branches of industry in which men have been completely replaced by women, who are now to be found in the distillery, the chemical factory, jute mills, saw mills, printing works, wood working factories, flour mills, soap works, foundries, and so forth. Shortage of labour, in fact, has for the most part been compensated for by the introduction of women, and there still appears to be an ample supply. The majority attracted by the high rate of wages and by the feeling that they are thus taking an active share in the war have found places in the munition works.

The question of the employment of women is further developed by Miss ANDERSON, the principal lady inspector of factories, in a special report dealing with the effect of the second year of war on the industrial employment of women and girls. She finds the 12 hour night shift for any length of time to be unthinkable for women except in extreme war emergencies, and then only if compensation in the shape of good food and general comforts is forthcoming. A very long night shift she would watch with suspicion, and would limit it to short periods for urgent necessities. But the same story is told, in Miss ANDERSON'S report, of the women's splendid spirit in working. Attention is very properly called to the pernicious effect of long hours on adolescent hands, who quickly develop symptoms of exhaustion and impaired vitality, but the facts have to be found out for them, as for the most part their idea is to keep on working. One of the girl hands said to the inspector, "It is the good cause that gives the good heart for work," and so some of the weaker in flesh, because of their willing spirit, exceed their physical capacity in bearing their share in the war's burdens. We can well understand how arduous has become the task of the Home Department in watching over the health interests of the great band of workers which has so suddenly been placed under the sheltering care of the provisions of the Factory Acts, and the administration may be congratulated on the admirable way it has adapted its machinery to deal with a situation so different from normal times, and which has presented so many new problems of extraordinary magnitude and difficulty.

SEXUAL ENLIGHTENMENT IN SECONDARY SCHOOLS

—At a meeting of headmistresses held at the Royal Society of Medicine on July 7th called to consider the recommendations of the Royal Commission on Venereal Diseases in reference to the education of young people in sexual physiology and hygiene Mrs Scharlieb M.D. pointed out that the question of combating venereal diseases was pre-eminently a women's question and dwelt on the part which the mistresses of secondary schools might play in the enlightenment of their pupils. A general request for further instruction was expressed and it was arranged for lectures to be given at the Royal Society of Medicine on Sept. 6, 7th and 8th at 5.15 to which all women teachers are invited.

Innotations.

Ne quid nlmis "

THE PUBLIC HEALTH CONDITION OF THE COUNTRY

WE publish in our Parliamentary report the statement made on Tuesday night in the House of Commons by Mr Long, the President of the Local Government Board, reviewing the work of his department, and it is with no small satisfaction that we record the broad message of that statement—namely, that the general condition of the country has never been more satisfactory. It is not only that pauperism has nearly vanished and that unemployment does not exist, but there has been a steady decrease in enteric fever and a high average standard of health, although enormous numbers of men have been suddenly collected in areas where, in the first instance at any rate, accommodation was necessarily of a makeshift nature. Mr Long said that, in spite of the shortage of medical men as a consequence of the war, the work of his department in the prevention and treatment of tuberculosis had not been allowed to fall into arrear, while child welfare schemes had been encouraged, and a grant had been made for the payment of health visitors in connexion with designs for safeguarding the health of expectant and nursing mothers and of infants. Lastly, Mr Long said that the Local Government Board had been able to adopt in large measure the recommendations contained in the report of the Royal Commission on Venereal Diseases, he spoke with confidence of the prospects of the co-operation between the Government, local and hospital authorities, medical men, ministers of religion, and the people generally, in the work of eradicating the evil.

STOCK MIXTURES UNDER THE INSURANCE ACTS

BEING authorised to do so under the new scale of dispensing fees set out in the 1916 Drug Tariff, the London Panel Committee has selected four stock mixtures from the 'Central List,' and any of these may be ordered for their insured patients by practitioners on the London panel one calendar month after the notice given by the Panel Committee of its selection. These will be dispensed at a reduced dispensary fee of 23d, and to secure the reduction the letters C.L. should be added after the name of the mixture. The mixtures in question have been placed on the list after consideration of their capability of being stocked in bulk without deterioration, and the formulae are commended to practitioners as a probable means of slightly reducing the cost of their drug bills and of facilitating their clerical work. The question of economy in prescribing, of which the free use of stock mixtures forms only a part is one of the principal difficulties which beset practitioners under the Insurance Acts. Many doctors have been surcharged for extravagance in the medicines ordered by them for their panel patients, and some of these were, no doubt, not so careful as they should have been in what is in effect authorising the expenditure of public money. On the other hand it can hardly have been the intention of those who were responsible for the scheme of National Insurance now in force that a medical man keeping his mental eye upon a prospective

bill for medicines, should prescribe for an insured patient as he would not do for one, not much better off financially, attended by him in his private practice. This, however, is what he must do, at least sometimes, if he would keep the average of his prescriptions low enough to avoid a surcharge. A medical man who has recently discussed this issue with the Secretary of the London Panel Committee has sent us a copy of his reply to an accusation of extravagance. In this it is pointed out with justice that a higher average cost of prescriptions may be a direct result of the greater individual care given to patients by a conscientious panel practitioner, and will in such a case be far more than compensated by a corresponding saving to the Sickness Benefit funds. It is not a question of considerably saving the pocket of a poor patient in a way which would not be necessary if he belonged to the affluent classes, but of bearing in mind the calls which the illnesses of other patients are making on the drug fund, and of sparing drugs accordingly. It is not right that such parsimony should be necessary. It is a parsimony not seriously affected by an infinitesimal saving in a dispensing fee here and there, but one which may affect the health of a patient, and militate against his speedy recovery. Incidentally we note a suggestion for economy in prescribing in an article contributed to the *Scotsman*, which recommends that elements introduced into a prescription purely as carminatives or for the purpose of flavouring and rendering the medicine less unpleasant should be omitted. The writer expresses the opinion that the abolition of such ingredients would probably effect a saving amounting to almost 10 per cent of the expenditure on drugs. As to how far this estimate may be correct we express no opinion, but the economy would in most instances be a legitimate one, and, further, might tend to prevent some persons from seeking medicine who would not greatly lose thereby. The saving effected would, however, only serve to lessen the strain upon the drug fund. It would have no effect in enabling the insured patient to be treated upon the same footing as his wealthier neighbour. In fact, it would rather tend to accentuate the difference between them.

THE LIFE-CYCLE OF THE SCHISTOSOME WORMS

DURING the past three years a considerable amount of time and work has been devoted to the life history of the schistosome worms parasitic in man. The first workers to obtain definite results were two Japanese observers, Miyata and Suzuki, who, in a series of observations and experiments, not only succeeded in tracing the whole of the life history of *Schistosomum japonicum* (the causative agent in Asiatic schistosomiasis) in the intermediate host, *Katayama nosophora* (a small mollusc with seven to nine spirals, very common in parts of Japan) but also in demonstrating its mode of entry into the definitive host. The observations recorded by these workers were confirmed by Leiper and Atkinson in 1914. In the early part of 1915 the War Office Bilharzia Mission (of which Dr R. T. Leiper, of the London School of Tropical Medicine, was in charge) proceeded to Egypt, and there succeeded in working out the life histories of those schistosome worms which produce vesical and rectal bilharziasis respectively. Three parts of the report of the

Bilharzia Mission have already been published in the July, August, and September (1915) issues of the *Royal Army Medical Corps Journal*, and the results obtained are briefly stated in the following account. When infected material containing the eggs of the bilharzia worms is passed into water the miracidia contained within them soon make their escape. In the water they swim about rapidly, by means of the cilia with which their cuticle is furnished, and eventually are attracted to one or other of the molluscs which is to function as their intermediate host for the ensuing period of their development. The cuticle of the mollusc is pierced with the aid of the small proboscis which protrudes from the anterior extremity of the miracidium, and having gained an entry the invader finds its way to the liver of its host. In the liver a series of changes take place in the form of the miracidium, and ultimately a complete metamorphosis results in the formation of the sporocyst. This latter is totally unlike the miracidium from which it arose, and is best described as a long, hollow, thin walled tube, which is unprovided with gut, glands, or suckers. The sporocyst is, however, capable, by a process of internal budding, of producing other sporocysts within itself. These latter, by simple rupture of the containing maternal wall, become free within the liver substance of their host, and it is in them that the next stage of the life cycle is evolved. In this second generation of sporocysts—the "daughter sporocysts"—internal budding again takes place. The development of these buds results in the formation of the cercariae—the final stage of evolution in the molluscan host. The cercariae are described as being possessed of a body and a tail, the latter being bifurcated at its extremity. The body is provided with two suckers, an oral and a ventral, and a bifurcated gut. No pharynx or eye spots are present. Between the bifurcations of the gut are several large glandular cells which communicate with the oral sucker by means of filiform ducts. The cercariae leave the sporocyst by rupture of the over distended maternal wall, and, after a shorter or longer period, are expelled from the body of the mollusc into the water, there to act as the infecting agents. The subsequent course of the life cycle was worked out by means of the experimental infection of rats, mice, guinea pigs, and monkeys, and it was demonstrated that two modes of infection are possible—viz., the cutaneous and the oral. It would appear, from the account given in the report, that the oral route is only different from the cutaneous in that whilst in the latter case the cercariae perforate the skin, in the former they perforate the buccal mucosa. In the case of a newly born mouse which had been immersed for half an hour in water which contained numerous cercariae, it was found when sections of the skin were examined that many of the cercariae had already perforated deeply into the skin, whilst in the water numerous detached tails were left. Three of four monkeys were subjected to infection with the bilharzia cercariae by pouring into the bottom of the cages in which they were confined water which had previously been infected. The fourth monkey was given infected water to drink. All four monkeys eventually died, and were found upon examination to be heavily infected. The monkey infected with drinking water showed earlier and more intense symptoms than the others. Leiper has been able to differentiate between the adult worms, which produce the terminal spined and lateral spined ova on morphological grounds. He states

that the molluscan intermediate hosts are also specific—in the case of *S. haematobium* being two species of *Bullinus* (*B. contortus* and *B. dybowskii*), and in the case of *S. mansoni* *Planorbis boissyi*. Dr F G Cawston reports in a letter appearing elsewhere in this issue that he has been successful in determining the intermediate host for the worm producing vesical bilharziasis in Natal.

THE SALE OF MEDICATED WINES

WE have received from the Central Control Board (Liquor Traffic) a copy of the General Order relating to the sale of medicated wines which comes into force on and after August 7th, 1916, in all areas to which the Defence of the Realm (Liquor Control) Regulations (1915) are applied. The Order provides that—

No person shall either by himself or by any servant or agent sell or supply to any person in any licensed premises for consumption off the premises or despatch therefrom any intoxicating liquor in the form of or prepared as (a) medicated wine or (b) any mixture or preparation which contains any drug or medicament or is sold or advertised for sale as containing or purporting to contain medicinal properties, except in a bottle or other vessel bearing a label correctly stating, in clear and legible words or figures the amount of proof spirit contained in such medicated wine or mixture or preparation. This Order is not intended to affect the sale of (1) any medicine, mixture, or preparation appearing in the British Pharmacopœia or the British Pharmaceutical Codex, or (2) any medicine, mixture, or preparation which is made up for a customer on the signed prescription of a medical practitioner, or (3) medicated or methylated spirits, or spirits made up in medicine and sold by medical practitioners or chemists or druggists. The chief object of this Order is, of course, to inform or perhaps warn the consumer that these wines in so many cases are potent alcoholic liquors. We should have thought that the disclosure of alcoholic strength in terms of actual alcohol would to most people have been more intelligible than in terms of proof spirit. It is not widely known that proof spirit means alcohol diluted practically a half with water, so that the figures for proof spirit would be double those for alcohol and the statement might well convey an exaggerated idea of alcoholic strength.

VENEREAL DISEASE IN SWEDEN

IN a paper by Dr Soderholm on venereal disease, on which we have already commented in THE LANCET of June 17th, an interesting account is given of the distribution of venereal disease in town and country in Sweden. It is a matter of common knowledge that the venereal diseases are mainly the products of large towns and industrial centres with a dense population. But hitherto there have not been many investigations showing how great the difference is between the incidence of venereal disease in town and country. When a modified form of compulsory notification of venereal disease was introduced in Sweden on Dec 30th, 1911, this difference soon became evident. This system of notification did not supply the names of the persons concerned but it did give the name of the place in which infection was supposed to have occurred. The figures for 1914 showed that in Stockholm the incidence of new cases of that in Stockholm was 217 per cent of the total venereal disease was 217 per cent of the total population. The incidence of the disease for the three towns Stockholm, Gothenburg, and Valmo was 149 per cent. For the smaller towns it was 026 per cent, and for the country districts it was

as low as 0.02 per cent. In the three large towns there were 1629 new cases of syphilis, 8168 new cases of gonorrhœa, and 1126 new cases of ulcus molle. While the total population of the three towns was only 665,638, the total population of the country districts was 4,156,717. Yet in the country districts there were only 121 new cases of syphilis, 666 new cases of gonorrhœa, and only 26 new cases of ulcus molle. It appears from these figures that the danger of infection from venereal disease is 75 times greater in the large towns than it is in the country districts and that far more active measures are required to combat the disease in the crowded communities than elsewhere. That the relative preponderance of venereal disease in the large towns coincides broadly with the incidence of prostitution is the inevitable conclusion from these facts and figures, and if the problems of venereal disease are those of prostitution it is only by reforms in the conduct of prostitution that an appreciable reduction of venereal disease can be anticipated. This, the moral of Dr Sederholm's communication, is a point of view not shared by all the other members of the Board of Health to which Dr Sederholm belongs. This body, apparently, is in favour of the abandonment of regulation of prostitution in any form, and relies mainly on educational methods and free treatment for every patient.

THE AUDIBILITY OF GUN-FIRING

SEVERAL correspondents have written recently calling attention to the unusual audibility of the gun firing in Flanders, so that a paper read at the last monthly meeting of the Royal Meteorological Society by Mr Miller Christy and Mr W Marriott has a topical interest. The audibility of the gun-firing in Flanders over the south east of England has been repeatedly noticed since an early period of the war, but Mr Christy says that undoubtedly the intensity of the sound varies considerably with the quality of the guns and the meteorological conditions. Sometimes slow and deliberate firing is heard at the rate of 3 to 12 shots a minute, each shot being quite loud and distinct. This is probably the firing of the monitors and other warships bombarding the German positions on the Belgian coast. Usually, however, the firing has been much more rapid, much less distinct, and apparently more distant. This is, no doubt, the sound of the fighting further inland—say, around Ypres, Dixmude, or Arras, it varies in rapidity from perhaps 4 or 5 shots to the minute up to more than 100. This sound is, as a rule, very faint, though easily perceptible and quite unmistakable, it resembles more nearly a dull and distinct thud, which is rather felt than heard. From the records collected it appears that the gun firing has been heard at one time or another over the counties of Essex, London, Kent, Surrey and Sussex, the most distant place being about 150 miles from Ypres. Mr Marriott, in discussing the meteorological conditions under which the gun firing was heard, said that the weather charts showed that generally there is a somewhat irregular, or not definitely defined, distribution of barometric pressure but mostly with a region of high pressure wedged in between areas of slightly lower pressure. These conditions are such as to produce light winds at the surface mostly between north and east over the neighbourhood of the North Sea. Aspect and elevation are also important factors for the hearing of the firing so that

there is nothing mysterious about the audibility altering so greatly as it obviously does. The weapon and its position, the weather and its modifications, all combine to make the audibility vary from day to day.

INDUSTRIAL ANILIN POISONING

THE paramount position of the anilin industry in Germany has naturally caused the experience of anilin poisoning to be mainly German. The production of anilin dyes in England consequent on the war is likely to familiarise us with anilin poisoning. The United States made no attempt to compete with Germany in the manufacture of anilin or anilin dyes until the supply was shut off by the war, but in the *Journal of the American Medical Association* Dr R V Luce and Dr Alice Hamilton now publish an important paper on Industrial Anilin Poisoning, based on experiences in the tyre factories of Akron, Ohio. Apart from the production of anilin colours, anilin is used in America in the compounding of rubber, especially for tyres, and in reclaiming rubber from scrap. When the war suddenly shut off the supply from Germany rubber manufacturers began to manufacture anilin, so that now to the men exposed to anilism in rubber manufacture must be added those engaged in producing the anilin. Industrial anilin poisoning, which a few years ago was negligible, suddenly assumed importance. So far the making of dyes is too new in the United States to furnish cases, those reported come from the rubber industry and from the use of a wash for printers' ink which contains anilin. The victims are known as "blue boys," from the cyanosis which is so prominent a symptom. Since the discovery of the cause of the trouble the rubber manufacturers have taken measures of protection, either by installing exhaust ventilators or simply by warning the men to seek the open air as soon as flushing of the face and violent headache come on. Pure anilin has never been known to cause poisoning, but pure anilin is not used in industry. What is known under this name is a mixture of anilin (amidobenzene) with metatoluidin, paratoluidin, orthotoluidin, and xylidin in varying proportions. Unlike most volatile poisons anilin gives no warning, for it does not irritate the eyes and throat. Yet according to the researches of Lehmann, anilin is toxic in even smaller doses than benzene, chloroform, or carbon disulphide. Most of the industrial cases follow spilling or splashing of anilin over clothes or skin, and doubtless both skin absorption and lung absorption play their part. Rambousek places anilin and all the nitro and amido derivatives of the aromatic series among the blood poisons the principal action of which is to cause the formation of methæmoglobin, in which the oxygen is firmly bound, thus producing a condition of "internal suffocation." In England Dr W Malden has examined the blood of men employed in the manufacture of anilin dyes and nitrobenzene. In about half he found a high red count with a low colour index and many imperfectly developed red corpuscles. The spectrum of methæmoglobin could be detected only when it was present in the proportion of 1 part to 10 of oxyhæmoglobin. Loss of hæmoglobin ran from 5 to 50 per cent. Stained specimens showed great variations in the size of the red corpuscles. Basophilic granules were found. Dr Malden believes that this is often the earliest sign of anilin poisoning, as it is of lead poisoning. The first

Bilharzia Mission have already been published in the July, August, and September (1915) issues of the *Royal Army Medical Corps Journal*, and the results obtained are briefly stated in the following account. When infected material containing the eggs of the bilharzia worms is passed into water the miracidia contained within them soon make their escape. In the water they swim about rapidly, by means of the cilia with which their cuticle is furnished, and eventually are attracted to one or other of the molluscs which is to function as their intermediate host for the ensuing period of their development. The cuticle of the mollusc is pierced with the aid of the small proboscis which protrudes from the anterior extremity of the miracidium, and having gained an entry the invader finds its way to the liver of its host. In the liver a series of changes take place in the form of the miracidium, and ultimately a complete metamorphosis results in the formation of the sporocyst. This latter is totally unlike the miracidium from which it arose, and is best described as a long, hollow, thin walled tube, which is unprovided with gut, glands, or suckers. The sporocyst is, however, capable, by a process of internal budding, of producing other sporocysts within itself. These latter, by simple rupture of the containing maternal wall, become free within the liver substance of their host, and it is in them that the next stage of the life cycle is evolved. In this second generation of sporocysts—the "daughter sporocysts"—internal budding again takes place. The development of these buds results in the formation of the cercariae—the final stage of evolution in the molluscan host. The cercariae are described as being possessed of a body and a tail, the latter being bifurcated at its extremity. The body is provided with two suckers, an oral and a ventral, and a bifurcated gut. No pharynx or eye spots are present. Between the bifurcations of the gut are several large glandular cells which communicate with the oral sucker by means of filiform ducts. The cercariae leave the sporocyst by rupture of the over distended maternal wall, and, after a shorter or longer period, are expelled from the body of the mollusc into the water, there to act as the infecting agents. The subsequent course of the life cycle was worked out by means of the experimental infection of rats, mice, guinea pigs, and monkeys, and it was demonstrated that two modes of infection are possible—viz., the cutaneous and the oral. It would appear, from the account given in the report, that the oral route is only different from the cutaneous in that whilst in the latter case the cercariae perforate the skin, in the former they perforate the buccal mucosa. In the case of a newly born mouse which had been immersed for half an hour in water which contained numerous cercariae, it was found when sections of the skin were examined that many of the cercariae had already perforated deeply into the skin, whilst in the water numerous detached tails were left. Three of four monkeys were subjected to infection with the bilharzia cercariae by pouring into the bottom of the cages in which they were confined water which had previously been infected. The fourth monkey was given infected water to drink. All four monkeys eventually died, and were found upon examination to be heavily infected. The monkey infected with drinking water showed earlier and more intense symptoms than the others. Leiper has been able to differentiate between the adult worms, which produce the terminal spined and lateral spined ova, on morphological grounds. He states

that the molluscan intermediate hosts are also specific—in the case of *S. haematobium* being two species of *Bullinus* (*B. contortus* and *B. dybowskii*), and in the case of *S. mansoni* *Planorbis boissyi*. Dr F. G. Cayston reports in a letter appearing elsewhere in this issue that he has been successful in determining the intermediate host for the worm producing vesical bilharziasis in Natal.

THE SALE OF MEDICATED WINES

WE have received from the Central Control Board (Liquor Traffic) a copy of the General Order relating to the sale of medicated wines which comes into force on and after August 7th, 1916, in all areas to which the Defence of the Realm (Liquor Control) Regulations (1915) are applied. The Order provides that—

This system of notification did not supply the names of the persons concerned, but it did give the name of the place in which infection was supposed to have occurred. The figures for 1914 show that in Stockholm the incidence of new cases of venereal disease was 2.17 per cent of the total population. The incidence of the disease for the three towns Stockholm, Gothenburg, and Malmö was 1.49 per cent. For the smaller towns it was 0.26 per cent, and for the country districts it was

CANADA

(FROM OUR OWN CORRESPONDENT)

The Ontario Health Officers' Association

THE fifth annual conference of the medical officers of health of Ontario was held in Toronto this year, Dr A. J. Macaulay, of Peterborough, discharging the presidential duties, and Dr John W. S. McCullough, chief health officer for Ontario, acting as secretary. Many interesting communications were read bearing on the public health of the province.

Dr M. B. Whyte, superintendent of the Isolation Hospital, Toronto, read a paper on the Quarantine Period for Measles, a disease which has been widely prevalent in Ontario the past six months, and from the discussion which followed the consensus of opinion of 400 health officers was that 18 days' exclusion from school following exposure was needless. It was agreed that those who suffer from the disease should be quarantined for seven days after the rash appears unless there are discharges or epistaxis, and that as second attacks are rare, those who have previously had the disease need not be quarantined at all.

Dr Fred Adams, epidemiologist to the Toronto Board of Health, gave a résumé of his observations upon typhoid fever in Toronto in the last six years, showing a remarkable improvement in the condition. In 1910 the death-rate from typhoid fever was 40 per 100,000, five years later, in 1915 it was only 1.9, the lowest rate of any of the large cities in America. The chief factors in this reduction Dr Adams ascribed to chlorination of the water supply, pasteurisation of milk, certified milk, and a campaign against flies and outdoor privies.

Dr J. G. Fitzgerald, of the Ontario Department of Health, read a paper on the Epidemic of Cerebro-spinal Meningitis which occurred among troops quartered in Toronto, and reported that "all the cases among troops in the Toronto Military District have recovered."

Among other interesting communications may be mentioned that of Dr W. H. Park, Director of the Public Health Laboratories, New York City, who, speaking on the treatment of diphtheria, advised the use of antitoxin in large doses, adding that the intravenous use of antitoxin was more effective than either the intramuscular or subcutaneous. In severe cases he gave, he said from 5000 to 15,000 units to a child, with correspondingly large doses in the adult. Laryngeal cases require early and large doses.

Major W. D. Sharpe (Brampton), who served as surgeon in the British Naval Hospital at Belgrade in the first year of the war, gave an interesting lecture on Sanitation in Serbia, and Captain Ruggles George A.M.C. (Toronto) told the interesting story of the first Canadian Overseas Contingent, taking the contingent from Camp Valcarter in Quebec to the trenches in Flanders.

Ontario Medical Association

The thirty-sixth annual conference of the Ontario Medical Association was held in Toronto at the beginning of June. Dr Harry B. Anderson (Toronto) presiding. Over 450 medical practitioners from all parts of the province attended. Dr Anderson in his presidential address discussed the important question of medical education in the province. He thought that there should be a strict uniform examination for the practice of medicine, and no granting of special privileges to those not fully trained and unequal to meet the requirements of the medical examination. He considered that from the standpoint of the medical profession the new Ontario Workmen's Compensation Act was most unsatisfactory in some particulars, notably the absence of a clause providing for the prompt and proper payment of the medical man for his services. Under this Act physicians in Ontario are practically compelled to attend injured workmen without pay. In dealing with the general organisation work of the profession in the province the President stated that there were now some 35 local medical societies in the province ready to affiliate with the Ontario Medical Association. He alluded also to the large number of Canadian practitioners engaged in the war. Professor A. D. Blackader (Montreal) said that after the war Canadian physicians should favour the home-made or British-made drugs as certain lines of drugs already made in Canada since the outbreak of the war had been entirely

satisfactory. At the conclusion of this paper the President stated that he had a communication from the Federal Government to the effect that it purposes revising the Patent Medicines Act and advising the association to make representations to the Government. A committee was appointed to take care of this matter. The therapeutics of pneumonia was discussed by Professor Solomon Solis Cohen, of Philadelphia, U.S.A., and Dr Elliott P. Joslin, of Boston, read a paper on the treatment of diabetes, recommending the cutting down of carbonaceous foods and the exclusion of fats until the patient was got into a state of moderate fasting. Dr John A. Wyeth, Dr John A. Bodine, and Dr C. H. Chetwood, of New York, explained the use of the moving picture in showing surgical technique. The demonstrations included hip-joint operations and kidney removals, and formed one of the features of the meeting. The following officers were elected—President Dr A. Dalton Smith, Mitchell, Vice-President Dr Clarence Starr Toronto, General Secretary Dr F. Arnold Clarkson, Toronto.

Toronto June 24th

NOTES FROM INDIA

(FROM OUR OWN CORRESPONDENTS)

Malaria Committees Abolished in the United Provinces

THE United Provinces Government has decided to abolish the provincial and divisional malaria committees which came into existence in the summer of 1910. A Government resolution explaining the reasons for this step says: "Some useful work has been done by provincial committees, but experience has shown that their duties which have consisted in collecting information and suggesting remedies for disease, overlap with those of the Sanitary Board. These duties will be transferred to the Sanitary Board, of which the Inspector-General of Civil Hospitals will now become a member. The duties assigned to divisional malaria committees were of a similar nature to those of provincial committees. The divisional committees have proved to be inadequately equipped for their duties." Malarial survey is a condition precedent to the initiation and elaboration of anti-malaria measures but it requires for its execution the service of experts and divisional committees have not and cannot well have at their disposal any expert agency. The surveys that have been made at Saharanpur, Kosi, Nagina and Lucknow have been the work of officers of the Sanitary Department, and all future surveys will be similarly initiated and controlled. In several divisions committees have already ceased to meet and in the remaining divisions the results achieved are not such as to justify their further retention.

The Bombay Medical Union

At the annual meeting of the Bombay Medical Union Dr H. S. Shroff, the President, delivered an address of wide political scope. Alluding to the enlistment of members of the "independent medical profession" by Government at the local war hospitals at base hospitals, and at several spheres of the war, he said that in the representation by the Bombay Medical Union to the Royal Public Services Commission it was stated that the cadre of the Indian Medical Service on the civil side could be reduced and could be replaced by civilian practitioners after competitive examination. It was in this way proposed that a civil medical department, when created, should form a reserve for the army in time of war, and since the outbreak of war 166 temporary commissions have been issued out of which 32 appointments of lieutenants in the Indian Medical Service were made in England and 134 in India.

With reference to the Bill to prevent the grant to unqualified persons of titles implying qualifications in Western medical science and the assumption and use by such persons of such titles or designations implying such qualifications, he said that the measure had been brought before the Council by "that sympathetic and statesmanlike member of the Council the Director General of the Indian Medical Service, who has been the custodian of the interests of that service and other services and keen to safeguard their interests and who is also keen to advance the status and aspirations of the Indian medical profession."

The third subject to which the speaker referred as one to which the Union had been giving special attention was the

symptoms are weariness or sleepiness, flushing of the face, a sense of fullness in the head and even of slight mental confusion, dryness of the throat, and dysphagia. The colour of the face changes from red to livid blue, which may increase to a deep purple. The pulse is rapid and weak, the temperature subnormal. Headache comes on early and is often violent, accompanied by dizziness and nausea, and in the more serious cases there is decided dyspnoea, increasing mental confusion, and finally loss of consciousness. These symptoms are due to want of oxygen. Later symptoms—icterus, methæmoglobinuria, bladder irritation, and bronchitis—are caused by the elimination of the poison. In some cases the subjective symptoms are slight and the man seeks advice because of his livid or blue colour, which is alarming to him and his friends. Usually industrial cases do not exhibit the severest symptoms, but epileptoid convulsions and protracted coma have occurred and proved puzzling to the medical attendant. Recovery in the milder cases is prompt, the men usually returning to work on the following day, though the cyanosis often persists for several days more. Chronic anilism is described by von Jaksch as a condition resulting from repeated doses of the poison so small as not to set up symptoms of acute poisoning. There are more or less headache, nausea, vertigo, muscular twitchings, disturbances of vision, sense of exhaustion, and loss of strength. The skin is usually livid, or it may be jaundiced. In one American case the man was treated for heart disease because of his cyanotic appearance and dyspnoea on exertion.

MEDICAL WOMEN'S FEDERATION

THERE has been for some years a Federation of University Women with the object of facilitating the expression of united opinion and the concerted action of University women on matters specially affecting them, and this federation has local associations in the cities of England, Wales, and Scotland, and is affiliated with similar associations in Ireland and India. An association of registered medical women was established more than 35 years ago. Other associations have since arisen, and it is now proposed to do for medical women what has already been done for University women in general by means of a federation of their existing associations. An application for incorporation has accordingly been made to the Board of Trade. The affairs of the federation are to be managed by an elected council, each association sending representatives in proportion to its numbers, and the first appointed representatives, of whom Miss A. Helen Boyle, M.D., is president, and Miss Jane Walker, M.D., provisionally secretary and treasurer, have drawn up a scheme which is being circulated to all medical women. At the central office a register of medical women will be kept indicating the type of work upon which they are engaged, the posts open to them, details regarding assistantships, and the sale and purchase of practices, and so forth. There is to be a salaried secretary at this office ready to give members any information and help that they desire. It is intended to take special steps to deal with public work in connexion with war emergency, school inspection, health insurance, public health and factory inspection in order to secure the fullest possible co-operation between the federation and the various Government departments concerned. The promoters hope

that every medical woman will join this federation and thus ensure its becoming a responsible professional body as well as a bond of communication between its members. The subscription has been fixed at one guinea entrance and one guinea annually, and intending members are asked to communicate at once with the secretary of the federation at 122 Harley Street, London, W. The federation is the natural result of the steadily widening sphere of woman in medicine.

TETRAGENUS SEPTICÆMIA

IN the *Annali di Medicina Navale e Coloniale*, issued from Rome by the Italian Admiralty, Dr. Dante Ferraro, a senior medical officer in the Italian Navy, details two cases of generalised infection by micrococcus tetrigenus which followed wounds of the feet and came under his notice in the naval hospital in Venice. In each case the wound of the foot seemed to heal, but two or three weeks later an indolent bubo formed and was opened. In each case there arose an endocarditis which ultimately led to the patient's invaliding out of the service. One also suffered from a tolerably severe nephritis. Dr. Ferraro quotes the case reported by H. Robinson in the *Journal of the Royal Army Medical Corps* for May, 1915, where an otorrhœa supposed due to typhoid infection was shown by blood culture to be caused by *M. tetrigenus*, and he notes that certain French authors who investigated by blood culture 738 cases of pyrexia in men who had undergone antityphoid inoculation, found in five the micrococcus tetrigenus which had not been previously suspected. It has been reported on ship board,¹ and Tremolieres and Loew, mentioning 25 cases of this septicæmia seen in French armies during the war, divide them into three classes: (1) benign, temperature not above 102°F, (2) severe, to 104°, lasting 8–10 days, and (3) a pleuro-pneumonia in which a few diplococci are found in blood culture along with a great majority of *M. tetrigenus*.

At the Royal Society of Medicine the Section of Surgery has arranged for a special meeting to be held on Friday next, July 21st, at 5 P.M., at which a paper will be read by Major Tait McKenzie, R.A.M.C., on "The Treatment of Convalescent Soldiers by Physical Means," illustrated by lantern slides of cases under treatment. Members of other sections are cordially invited, and the paper will have special interest for members of the Sections of Balneology, Electro-therapeutics, and Neurology.

THE death is announced of Dr. Walter William Hunt Tate, obstetric physician to St. Thomas's Hospital. We hope to publish a full obituary notice later.

¹ Home. THE LANCET, June 12th 1903, p. 171.

DONATIONS AND BEQUESTS.—By will the late Mr. Lestock Robert Friskine left £200 each to the London Liver Hospital, the Royal Berks Hospital, and the London Hospital. The late Mr. B. H. Deakin, town clerk of Monmouth, bequeathed £500 to the Monmouth General Hospital and Dispensary for the maintenance of a children's ward in memory of his daughter.

WATER SUPPLY OF BIDEFORD (DEVON).—The Bideford town council has adopted a scheme for augmenting the water supply of the town at an estimated cost of £135,000. A new reservoir is to be erected capable of holding 27,000,000 gallons to be supplied from a collecting area of 600 acres, and this would be capable of yielding at least 3,500,000 gallons per annum.

THE SERVICES

INDIAN MEDICAL SERVICE EXAMINATIONS

It was recently announced that after the open competitive examination held last July for admission to the Indian Medical Service no similar examination would be held during the continuance of the war, but that such appointments as might be required to meet the absolutely indispensable needs of the Service would be made by nomination by the Secretary of State. To assist him in making these appointments which, as already announced, will be limited in number to the absolutely indispensable needs of the Service, Mr Chamberlain has appointed a Selection Committee who will summon and interview such applicants as may appear to be *prima facie* suitable, and make recommendations for appointment. Applications for appointment should be addressed to the Secretary of the Military Department, India Office, Whitehall S.W., and should contain concise particulars of the applicant's medical degrees and career. Applicants must be over 21 and under 32 years of age at the time of application. Particulars regarding pay, promotion, &c., in the Service can be obtained from the Secretary, Military Department.

ROYAL ARMY MEDICAL CORPS

Temporary Captain Fred W Mackenzie (retired pay) relinquishes his commission on account of ill health.

Temporary Lieutenants to be temporary Captains: A. L. Thorner, R. P. Williams, T. E. Ferguson, I. W. Magill, H. H. Taylor, G. Fleming, C. G. Macfar, J. N. F. Fergusson, C. Price-Jones, C. P. Symonds, G. Pollock, F. T. Rees, F. D. Johnson, J. M. Anderson, R. D. Clarton, T. J. Lydon, R. A. Facey, M. J. Houghton, R. S. Armour, W. Templeman, W. S. O. Waring, C. B. Kidd, P. M. MacLachlan, H. B. Lawson, A. Hipwell, H. V. Walsh, G. K. Thompson, D. B. Pascall, F. I. MacKinnon, J. C. McKerrrow, T. P. Seymour, E. K. Gawn, D. Gillespie, J. W. Pettinger, H. M. Macgill, W. S. Finch, R. J. Harris, H. F. Holmden, C. G. Munro, H. G. Dressing, J. H. K. Sykes, C. K. McKerrrow, J. T. Myles, J. I. Arnold, V. E. Badcock, W. H. Scott, H. H. Sloane, E. R. Fothergill, J. B. T. Keswick, L. Game, W. T. Williamson, W. Macleod, A. Mathieson, W. S. B. Hay, D. Fletcher, D. A. Donald, T. L. Fleming, C. B. Wainwright, T. W. Buckley, R. A. H. Fulton, C. N. Corbett, C. C. Worster Drought, H. T. Lippiatt, S. J. Staples, M. Douglas, J. H. White, and A. Drouin.

Temporary Lieutenants relinquishing their commissions: G. W. Deeping, E. M. Rooke, E. L. Hucker, R. H. Williams, C. S. Thomson, R. H. Mercer, W. R. Morris, L. O. Weinman, G. W. Dryland, W. Bates, W. Doyle, E. Ryan, C. S. Wood, A. J. Lomas, O. S. Wraith, D. C. Laird, B. H. Greensill, A. J. V. McDonnell, J. C. Walker, C. H. Sills, A. Bryans, E. R. R. Chesman, H. G. Kilner, H. S. C. Darbyshire, R. Nairn, A. J. Turner, F. Copeland, R. V. G. Monckton, R. Rennie, T. R. Earls, Davis, J. D. MacKay, J. G. McLeod, M. J. Vigneux, E. V. Sullivan, W. E. Campbell, G. S. Williams, and F. J. Sadler.

To be temporary Lieutenants: A. Dewar, D. P. Blair, A. R. M. Brennan, J. Clark, R. E. Marwick, G. P. G. Beckett, C. F. Davey, W. St. A. Hubbard, A. P. Robertson, J. P. Mathie, J. A. B. Hammond, D. D. Pincock, T. S. Law, E. G. H. Weir, J. B. Donaldson, G. D. Watkins, J. D. Doherty, J. M. Lazenby, R. R. Law, H. R. Mayo, and C. W. Brown.

P. D. Magowan to be temporary Lieutenant whilst employed at the Lord Derby War Hospital.

Canadian Army Medical Corps: Lieutenant F. H. Wheeler to be temporary Captain.

TERRITORIAL FORCE

Army Medical Services

Lieutenant Colonel F. Kelly, Highland Field Ambulance, to be Assistant Director of Medical Services, a Mounted Division with temporary rank of Colonel.

Captain W. T. Rowe from Attached to Units other than Medical Units to be Deputy Assistant Director of Medical Services a Mounted Division.

Royal Army Medical Corps

Lancashire Field Ambulance: Captain A. Callam to be temporary Lieutenant Colonel whilst commanding a Field Ambulance. Captain (temporary Major) H. W. Pritchard to be Major.

London Field Ambulance: Captain (temporary Lieutenant Colonel) G. L. L. Lawson relinquishes his temporary rank on command to command a Field Ambulance.

Northumbrian Field Ambulance: A. F. Raine to be Lieutenant.

Wessex Field Ambulance: Captain P. R. Bolus from Attached to Units other than Medical Units to be Captain.

Eastern General Hospital: Lieutenant Colonel Sir T. Clifford Allbutt, K.C.B., F.R.S., relinquishes his commission.

North Midland Field Ambulance: Captain W. B. Williams relinquishes his commission.

East Anglian Division: Sir T. Clifford Allbutt, K.C.B., F.R.S., late Lieutenant Colonel, Eastern General Hospital, is appointed to the Hon. Colonelcy of the R.A.M.C., East Anglian Division.

West Lancashire Field Ambulance: Major W. Macdonald to be temporary Lieutenant Colonel whilst commanding a Field Ambulance. Captain M. I. Dick, from West Lancashire Field Ambulance, to be Captain.

Home Counties Division Sanitary Section: Lieutenant F. T. H. Wood to be Captain.

Welsh Casualty Clearing Station: Lieutenant A. W. Clarke to be Captain.

Attached to Units other than Medical Units—Captain R. P. Ryan, from a Wessex Field Ambulance, and Captain H. G. Dodd, from a Northern General Hospital, to be Captains. Temporary Lieutenant C. A. E. I. Brownlee, from Royal Regiment of Artillery, and T. Higson to be Lieutenants.

VOLUNTEER OFFICERS' DECORATION

Surgeon Major W. Richardson, Isle of Man Volunteers, has received the Volunteer Officers' Decoration.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

In the 95 largest English and Welsh towns with populations exceeding 50,000 persons at the last Census, 7922 births and 3693 deaths were registered during the week ended Saturday, July 8th. The annual rate of mortality in these towns which had been 12.3, 12.6, and 11.6 per 1000 in the three preceding weeks, fell in the week under notice to 11.1 per 1000 of their aggregate civil population estimated at 17,312,295 persons for the year 1915. During the 13 weeks of last quarter the mean annual death rate in these towns averaged 14.3, against 15.8 per 1000 in London. Among the several towns the death rate last week ranged from 4.6 in Wimbledon, 4.7 in Ealing, 5.0 in Leyton, 5.5 in Eastbourne, and 5.8 in Gillingham and in Bournemouth, to 16.0 in Huddersfield, 16.1 in Lincoln and in Rochdale and 16.4 in Walsall and in Darlington.

The 3693 deaths from all causes were 159 below the number in the previous week, and included 224 which were referred to the principal epidemic diseases, against numbers declining from 335 to 225 in the five preceding weeks. Of these 224 deaths, 61 resulted from whooping cough, 60 from measles, 54 from infantile diarrhoeal diseases, 35 from diphtheria, 9 from enteric fever, and 4 from scarlet fever but not one from small pox. The annual death rate from these diseases was equal to 0.7 per 1000 and coincided with that recorded in each of the three preceding weeks. The deaths attributed to whooping cough, which had been 76, 77, and 55 in the three preceding weeks, rose to 61 and included 11 in London, 5 each in Birmingham and Sheffield, 4 in Sunderland, and 3 in Oldham. The deaths referred to measles, which had been 65, 67, and 68 in the three preceding weeks, fell to 60, and caused the highest annual death rates of 1.1 in Sheffield, 1.5 in Oldham, 1.6 in Wolverhampton, 2.3 in Gillingham, and 3.1 in Dudley. The deaths of infants (under 2 years) from diarrhoea and enteritis which had been 52, 45, and 50 in the three preceding weeks rose to 54 of which 19 were registered in London, 5 in Liverpool, and 3 in Nottingham. The deaths attributed to diphtheria, which had been 34, 27, and 29 in the three preceding weeks, rose to 36, and included 14 in London and 3 each in Tottenham and Birmingham. The deaths referred to enteric fever which had been 11, 13, and 10 in the three preceding weeks numbered 9 and included 2 each in Manchester and Bradford. The fatal cases of scarlet fever, which had been 9, 15, and 13 in the three preceding weeks fell to 4 of which 2 occurred in London.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 1302, 1303, and 1273 at the end of the three preceding weeks further fell to 1252 on Saturday last, 170 new cases were admitted during the week, against 149, 171, and 162 in the three preceding weeks. These hospitals also contained on Saturday last 1303 cases of enteric fever, but not one of small pox. The 857 deaths from all causes in London were 16 fewer than in the previous week and corresponded to an annual death rate of 10.7 per 1000. The deaths referred to diseases of the respiratory system which had been 137, 157, and 107 in the three preceding weeks, fell to 95 in the week under notice.

Of the 3693 deaths from all causes in the 95 towns 125 resulted from violence and 25 were the subject of coroners' inquests while 1163 occurred in public institutions. The causes of 34, or 0.9 per cent. of the total deaths were not certified either by a registered medical practitioner or

foundation of a new college in Bombay. The trustees of the late Seth Gordhandas Sunderdass Charities have offered to the corporation the princely donation of Rs 12 lakhs from their funds for founding a medical college in Bombay. The corporation has taken an enlightened view of the proposal and has asked their Medical Relief Committee to report on its practicability. "The Bombay Medical Union," said their President, "is delighted with the offer, considering it to be conceived in the interests of medical science by the indigenous qualified profession. The present system of medical education in India was conceived in 1845 when not a single Indian was possessed of Western medical education and qualification. Naturally, officers of the Indian Medical Service in the employ of the Government were put in charge of teaching colleges like the Grant Medical College on our side. To those pioneers of medical education we owe a deep debt of gratitude for their unselfish efforts in the cause of medical education. But the pupils of the college, owing to the system of the covenants on which the European teachers were engaged when coming out to India, could not become teachers in their own college, though certain appointments have been made in the junior subject of botany." Dr Shroff added that recently under the stress of war three appointments from among the Indian medical profession had been made to professorial chairs.

Shortage of Medical Men

The Government of India have had under consideration the question of offering enhanced terms to civil sub-assistant surgeons on military duty, including those already employed, who undertake liability for field service out of India and on expeditions based on the frontiers of India during the present emergency. They have now decided that each civil sub-assistant surgeon on signing the declaration, undertaking the liability to proceed on active service when ordered, will receive his civil pay plus military pay plus compensation for loss of private practice, plus an outfit allowance, free rations and the usual service concessions for families. These liberal terms ought to draw a very large number of these men from civil to military employ, more especially as in addition to the above each sub-assistant surgeon will receive permanent promotion without departmental examination to the next higher grade should such promotion become due whilst in military employment, provided that he has a good record of service generally and has been reported on by the military authorities as fit for promotion. Further, it has been specially provided that the civil prospects of such civil sub-assistant surgeons as volunteer for field service shall not be adversely affected. The fact of undertaking liability for field service will on the contrary, be taken into account as conferring a special claim to consideration hereafter should prospects of promotion offer for which the sub-assistant surgeon is otherwise fit.

Plantain Juice as an Antidote for Snake bite

I recorded recently a case of alleged cure of snake bite at Colombo by the use of plantain juice.² A case of snake bite at Serampore will therefore be of interest where plantain juice was used. A servant, of the principal of the Government Weaving College was bitten by a venomous snake in the foot. The principal applied a ligature eight inches above the bitten part and then cut it with a lancet and applied permanganate of potash making the wound bleed freely. He then extracted some juice from a plantain tree and gave the patient about a cupful to drink. After drinking the plantain juice the man seemed to recover a little and the wound was washed. He was made to walk up and down, and in the morning when the ligature was removed, the man was declared cured.

June 10th

* THE LANCET April 1st 1916 p 745

THE RESEARCH DEFENCE SOCIETY—The annual general meeting of this society has been postponed owing to the war many of its members being engaged on active service while others have their time fully occupied in various kinds of work on behalf of the sick and wounded in this country. But the propaganda work of the society is still actively carried on under the direction of Mr Stephen Paget. Among the most recent literature issued by the society are reprints from the *Field* and *English Mechanic* bringing before the public in clear language the value of scientific pathological work both to our Army and to the civilian population.

ASYLUM REPORTS

Kingseat Mental Hospital (Aberdeen City District Board of Control) (Annual Report for the Year 1915)—The total number of cases under treatment during the year was 665, the average daily number resident being 527. The number of admissions amounted to 171, of which 49 were transferred from other asylums. Of those admitted 2 were not insane, 44 were curable, 107 were absolutely incurable, and in 18 the prospect of recovery was doubtful. The most prevalent forms of disease were those embraced under the term manic depressive insanity, imbecility and idiocy, the alcoholic psychoses, primary dementia of adolescence, epileptic insanity, and arterio-pathic and senile dementia. With regard to the duration of illness prior to admission it was found that of the direct admissions 93 had been mentally ill for less than three months, 8 for less than 12 months, and the remainder for over 12 months. Hereditary predisposition was present in 33 cases and 18 had suffered from one or more previous attacks. The discharges during the year numbered 75, the percentage of recoveries on the admissions being 32.1, which was 4 per cent lower than in the previous year. This decrease was due to the admission of 40 incurable patients from Edinburgh and Glasgow respectively. Excluding these extraneous admissions, the percentage of recoveries among the Aberdeen admissions was 40.4, being 4 per cent higher than in 1914. There were 50 deaths—29 men and 21 women, of these, 12 were over 70 years of age. The war has had so far practically no material effect on the admission rate.

Middlesbrough County Borough Mental Hospital (Annual Report for the Year 1915)—The total number of cases under treatment during the year was 639, with an average daily number resident of 472. The admissions, which totalled 207 included 116 cases transferred from Newcastle City Asylum in April. There were 79 from the borough, a decrease of 5 as compared with the previous year but the number resident was increased by 9. The proportion of the insane to the estimated population of the borough was 1 to 402, or 24.8 per 10 000 the figures for England and Wales being 1 to 266, or 37.6 per 10 000. The total number of discharges, 96 included 54 patients transferred to Chester Asylum. The recoveries were 30, making a recovery rate of 37 on the direct admissions. The report states that one of the patients who escaped was a man who had been in the asylum since shortly after it was opened in 1898. He was ordinarily well behaved and was allowed a good deal of liberty, but he had a habit of talking to himself and cursing imaginary enemies while at work. One morning he did not return to breakfast and when next heard of he was with the Royal Engineers in Flanders. The deaths numbered 58 making a rate of 12.2 on the average daily number resident. Post-mortem examination was made in 41 cases. There were 17 private patients on the register at the end of the year 4 having been admitted, 1 discharged recovered and 6 having died during the year.

County and City of Worcester Lunatic Asylum (Annual Report for the Year 1915)—The total number of cases under treatment during the year was 1531, the average daily number resident being 1252. There were 405 admissions, of which 144 were direct the remainder being transferred from other asylums. The discharges numbered 83 of which 59 were recovered making a recovery rate of 40.95 per cent on the direct admissions. One patient was discharged "not insane." A male patient was prosecuted for a murderous assault on the son of the medical superintendent. He was found "Guilty but insane." He was removed to a criminal asylum. An interesting medico-legal feature was that the man appealed against the verdict. The Court of Appeal held that the verdict "Guilty but insane" was no a conviction, and that a man who was not convicted could not appeal. There were 93 deaths making a death rate of 7.9 per cent on the daily average number resident. The principal causes of death were as follows: Pulmonary tuberculosis 21, heart disease 20, senile decay 17, epilepsy 8 and pneumonia 6. Post-mortem examinations were held in 63 cases a percentage of 69.8. On Jan 1st 1915 there were 24 private patients in residence. Four females were discharged. One male and two females died. On Dec 31st 1915 there were 19 remaining.

THE PREVENTION OF BILHARZIA INFECTION

To the Editor of THE LANCET

SIR,—I have found that 116 out of 596, or 19 per cent., of the fresh water snails of Natal harbour cercariae at this period of the year. Of those infected, 76 contain "tadpole" forms and 40 contain cercariae with bifid tails. So far, these latter have only been found in one species of snail, *Physopsis africana*. The cercariae with bifid tails are of five varieties. One of them possesses eye spots and is similar to that which has been associated with bilharzia disease amongst birds in Egypt. This form is uncommon. Another possesses a muscular pharynx, this also is a rare form. The cercariae which answer to the description of those which cause bilharzia symptoms in man and beast in Egypt and the Far East are the more common of the forms with bifid tails met with in Natal, being found in 14 per cent of the specimens of *Physopsis* collected from Durban and in 15 per cent of the specimens collected from the Umsinduzi river at Pietermaritzburg. One common form has very long prongs to the tail and is considered to be an avian trematode, the other has fan like prongs to the tail and is believed to be the human form.

Of 31 specimens of *Physopsis africana* from the Umsinduzi river which I exposed to infection by miracidia obtained from the urine of a patient suffering from bilharziosis on March 31st, 14 specimens, or 45 per cent, contained cercariae with bifid tails on April 22nd, whilst 6 young sporocysts were found in specimens of the same snail within 14 days after being exposed to infection in the same way. In 4 of these small cercariae with bifid tails were seen, in the other 2 the cercariae were young and ill defined.

I am, Sir, yours faithfully,

F G CAVERTON, M B, B O Cantab

Pietermaritzburg Natal May 13th 1916

THE EFFECT OF FERRIVINE AND INTRAMINE ON SYPHILIS

To the Editor of THE LANCET

SIR,—In order to advance our knowledge of chemotherapy I asked Lieutenant-Colonel L W Harrison and Captain C H Mills to kindly persuade the eminent chemists, whom my work on the subject has bewildered, to come forward and discuss the statements which are said to be contrary to the knowledge we possess. Instead they again quote Professor Bayliss, who I am sure would never have raised the objections he did had he studied my research work or repeated those experiments upon serum which formed the foundation of that work. Furthermore, all Professor Bayliss's objections were met by me in a letter which was published before Colonel Harrison and Captain Mills wrote the letter which appears in your issue of July 1st. Professor Bayliss was the only speaker who criticised my views, therefore from the use of the word "chemists" there must still be at least one other who is hiding his light underneath a bushel. It is true that another speaker—namely, Dr C H Browning, whom Colonel Harrison and Captain Mills quote—associated himself with Professor Bayliss. Perhaps Colonel Harrison and Captain Mills will either prevail upon Dr C H Browning to come forward or will take it upon themselves to point out the highly speculative assertions to which they allude. A little discussion on this aspect of the subject would I venture to think lead to the dealing of the death blow to Ehrlich's theory of chemotherapy which is not only the acme of speculation but illogical from start to finish. Your readers have probably noticed that not one single word in support of Ehrlich's views has emanated from one of those who appear to be so troubled by my own.

The mention of the *Sp pallida* in the next paragraph only leads me to state once again that unless my work on the leucocytocoon syphilids be repeated, it will be impossible for the critics to understand fully the other links in my chain. The *Sp pallida* is not the cause of syphilis and its death should not be our main aim in chemotherapy, the spore being the place we should strive to kill. Now the spore is uninfluenced by salvarsan while the *Sp pallida* is killed almost instantaneously, therefore salvarsan does not cure syphilis, a fact we should all know but do not realise. From the 400 odd injections of

ferrivine and intramine I have administered, I have proved, I think beyond all doubt, that ferrivine will do exactly what salvarsan will not do and *vice versa*. Ferrivine will remove indurative chancres, lymphangitis, and lymphadenitis, which salvarsan will not, but it will not cause the uniform disappearance of mucous papules, lesions which are particularly sensitive to salvarsan. Intramine acts as a complement to any metallic compound, and has caused lesions to disappear which have either been aggravated or have not responded to salvarsan. The rapidity with which intramine will remove the induration of chancres and the resistant skin papules is extraordinary. If Colonel Harrison and Captain Mills's experience gave them results different from those obtained by myself, would it not have been more in the interests of science if they had tried to find out wherein the difference lay, instead of stating that they had obtained such and such results, therefore the action of intramine and ferrivine is absolutely nil. No object would have been gained in my opening this discussion if the sulphur and iron compounds were perfect. We are now in the position of being able to abolish the worship of the German syphilitic trinity (*Sp pallida*, Wassermann reaction, salvarsan) and to strike along paths of our making, hence my object in wishing for a discussion was to seek co-operation with a view to perfecting a non toxic metallic compound which would render the use of the toxic element arsenic superfluous.

Before closing this letter I should like to point out that, with a view of rendering rational chemotherapy a British product, I handed over (December, 1915) a copy of my first paper on the subject before it appeared in THE LANCET (January, 1916) to the National Medical Research Committee, offering at the same time to lay the proofs of my statements before them and as much of the drugs to experiment with as might be required. No representative of that committee came to see me, or visited the Lock Hospital, or wrote for supplies of the drugs. In March, 1916, I wrote asking for the report of the investigations which had been promised me. All I received was the return of my paper. I sincerely trust that Colonel Harrison and Captain Mills will continue this discussion.

I am, Sir, yours faithfully,

Wimpole-street W July 2nd 1916 J E R McDONAGH

SCARLET FEVER CARRIERS

To the Editor of THE LANCET

SIR,—In reference to Dr Donald Hood's letter in your issue of July 1st re the infectious condition of patients desquamating after scarlet fever, the following case is of interest.

The patient, a girl aged 4, was admitted to the London Fever Hospital on Jan 6th suffering from a mild attack of scarlet fever. The temperature rose to 101°F on the second day of illness and then fell to normal. There were no complications of any kind, and the child was discharged six weeks later quite well with no trace of desquamation. At no time was there any discharge from the ear or nose. She went to stay in the country with three elderly ladies. Ten days after she had been there one of these contracted scarlet fever and subsequently died. A sister who nursed her also contracted scarlet fever. The child, who was in perfect health and free from any trace of desquamation, then went home. On March 18th—i.e., a month after the child had left the fever hospital—her brother came home from school to spend the week end. He contracted scarlet fever on March 23rd, had a mild attack, and recovered. When at home he had kissed his sister. Whether or no desquamation is in itself infectious is a disputed point. In this instance there was no trace of desquamation, but it is clear that the child was a scarlet fever carrier. I think there can be little doubt that the infection here lurked in the throat but in our ignorance as to the nature of the organism responsible for scarlet fever it is impossible to detect carriers. I am, however, convinced from this and other similar cases that there are scarlet fever carriers who are not desquamating and have no nasal or aural discharges, and it seems practically certain that the infection is conveyed by the scarlet fever organism in the throat, which may in certain cases retain its vitality for a prolonged period, in the same way as the diphtheria bacillus in diphtheria carriers.

I am, Sir, yours faithfully

July 2nd 1916

JOHN F H BROADBENT

by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Sheffield, Leeds, Bristol, Bradford, and in 57 other smaller towns. Of the 34 uncertified causes, 6 were registered in Liverpool, 5 in Birmingham, 3 in Manchester, and 2 each in Stoke-on-Trent, Barrow-in-Furness, and Middlesbrough.

HEALTH OF SCOTCH TOWNS

In the 16 largest Scotch towns with an aggregate population estimated at 2,372,000 persons at the middle of this year, 1067 births and 563 deaths were registered during the week ended Saturday, July 8th. The annual rate of mortality in these towns, which had been 12.2, 13.4, and 12.6 per 1000 in the three preceding weeks, fell to 12.4 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death rate in these towns averaged 15.3, against 14.3 per 1000 in the large English towns. Among the several towns the death rate last week ranged from 1.6 in Ayr, 6.9 in Clydebank, and 9.0 in Dundee, to 15.5 in Paisley, 18.7 in Perth, and 19.6 in Kilmarnock.

The 563 deaths from all causes were 11 fewer than the number in the previous week, and included 46 which were referred to the principal epidemic diseases, against numbers increasing from 39 to 54 in the three preceding weeks. Of these 46 deaths, 19 resulted from measles, 8 each from scarlet fever and whooping-cough, 5 each from diphtheria and infantile diarrhoeal diseases, and 1 from enteric fever, but not one from small pox. The annual death rate from these diseases was equal to 1.0, against 0.7 per 1000 in the large English towns. The deaths attributed to measles, which had increased from 13 to 28 in the four preceding weeks, fell to 19, and included 10 in Glasgow and 2 each in Edinburgh, Dundee, Leith, and Greenock. The deaths referred to whooping-cough, which had been 7, 4, and 5 in the three preceding weeks, rose to 8, and comprised 5 in Glasgow, 2 in Aberdeen, and 1 in Coatbridge. The fatal cases of scarlet fever, which had been 6, 7, and 1 in the three preceding weeks, rose to 8, and included 4 in Paisley, 3 in Glasgow, and 1 in Kilmarnock. The 5 deaths attributed to diphtheria, of which 2 occurred in Edinburgh, were slightly below the average in the earlier weeks of the quarter. The deaths of infants (under 2 years) from diarrhoea and enteritis, which had been 4, 11, and 13 in the three preceding weeks, fell to 5, and included 3 in Glasgow. The fatal case of enteric fever was registered in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 75, 75, and 57 in the three preceding weeks, rose to 64 in the week under notice, but were 12 below the number registered in the corresponding week of last year. The deaths from violence numbered 23, against 28 and 22 in the two preceding weeks.

HEALTH OF IRISH TOWNS

In the registration area of Dublin 240 births and 134 deaths were registered during the week ended Saturday, July 8th. The annual rate of mortality, which had been 17.8, 15.9, and 17.3 per 1000 in the three preceding weeks, was 17.6 in the week under review, against 10.7 and 12.9 per 1000 in London and Glasgow respectively.

Of the 134 deaths at all ages, 28 related to infants under 1 year and 39 to persons aged 65 years and upwards. The deaths referred to the principal epidemic diseases numbered 12 and comprised 8 from infantile diarrhoea, 2 from scarlet fever, and 1 each from enteric fever and whooping-cough.

The causes of 4 deaths were uncertified, and 1 other was the subject of a coroner's inquest while 48 or 36 per cent, of the total deaths occurred in public institutions.

During the same period 199 births and 93 deaths were registered in the city of Belfast. The deaths corresponded to an annual rate of 12.4, or 1.1 per 1000 less than in the previous week, and included 14 of infants under 1 year and 24 of persons aged 65 years and upwards. Two deaths were referred to measles and 1 each to whooping-cough and infantile diarrhoea. The causes of 2 deaths were uncertified and 1 other was the subject of a coroner's inquest, while 24 occurred in public institutions.

A SPECIAL prize Fellowship of £100, offered by the Federation of University Women to encourage research on some questions of special interest in the present national crisis has been awarded to Dr. Alice Lee, Fellow of University College London, who is about to undertake an investigation into the birth rate as affected by present conditions.

EDINBURGH FACULTY OF MEDICINE. THE ADMISSION OF WOMEN.—The recommendation of the Senatus Academicus that the classes in the Faculty of Medicine should be open to women was discussed by the University Court on Monday last and the principle agreed to. A committee was appointed to prepare a scheme to carry out the recommendation.

Correspondence.

"Audl alteram partem."

THE NATURE OF THE CHANGES WHICH OCCUR IN MUSCLE AFTER NERVE SECTION

To the Editor of THE LANCET

SIR,—In your issue of July 1st there appeared a very interesting paper by Professor J. N. Langley on the above subject, concerning which I may perhaps be permitted to make a few comments from the clinical point of view.

1. Professor Langley suggests that the wasting of muscles after nerve section may be a "fatigue atrophy," owing to their being in a state of constant fibrillation. While continuous over fatigue may explain their diminution in size, it obviously cannot account for these changes in electrical response. For these changes may persist after the muscle has apparently recovered and is again of normal size.

2. Reference is made to a paper of mine in which I advocated rhythmical tetanising contractions in the treatment of nerve muscle injuries. I was careful to explain, however, that such treatment presupposed that it was desirable to cause contraction of some sort in any given case, and my contention was that rhythmical tetanising contractions were more effective than "galvanic twitches" or single condenser impulses. But I should not like it to be thought that I advocate contraction provoking currents in every case of nerve injury. In cases of complete nerve severance where end-to-end union has been performed, artificially provoked contraction may be actually harmful in the early months. A mild sinusoidal bath is the most that should be used until there is some definite sign that the nerve trunk is again conducting motor impulses. This may be shown either by (a) improved condenser response in the muscle itself, (b) signs of electrical conductivity in the nerve when stimulated above the site of injury, (c) faint return of voluntary power. When this stage of recovery has been reached my experience is that rhythmical tetanisation of the muscles, either by direct stimulation or by exciting the motor nerve, becomes of vastly greater value than the sinusoidal bath or even than "single impulse" contractions. The greatest care must however be exercised not to over fatigue the muscles.

3. With regard to the mode of disappearance of the electric responses after complete nerve blockage, observations with the condenser instrument show that the process is gradual, from 8 to 12 weeks being occupied in some cases before the extreme grades of the Lewis Jones scale are reached. This assumes a constant voltage of 100—the only change being in the size of condenser, and consequently the length of impulse employed. If the voltage be raised, a shorter impulse suffices. Not only so but if a tetanising discharge is being used—as in my modification of the original Lewis Jones instrument—the more rapidly the impulses succeed each other the greater the effect even though the individual impulses remain of the same length. It is thus easy to believe that sufficiently violent faradism might be able to cause contraction in any muscle, no matter how long severed from its motor nerve. From the clinical point of view, however, we are able to say that certain conclusions sufficiently accurate to be of practical use may be drawn from the response of muscle and nerve to electrical impulses of definite length delivered at a fixed voltage and under standardised conditions which admit of exact reproduction by various observers.

In conclusion I would respectfully press upon the notice of the pure physiologists the old adage that science is measurement, and urge them to abandon in their experiments the use of an instrument so notoriously incapable of standardisation as the faradic coil.

I am, Sir, yours faithfully

F. HERMAN JOHNSTON

ATROPA BELLADONNA

To the Editor of THE LANCET

SIR,—My attention has just been called to an annotation on the Cultivation of Medicinal Herbs which appeared in THE LANCET on June 17th in which the passage occurs "Belladonna is a weed in this country." I am inclined to think this must refer to the woody nightshade (*Solanum dulcamara*), and not to the official plant *Atropa belladonna* does grow wild but not to a very large extent, a mature plant is shrub-like, 4 to 5 feet high, with as many as 20 stout stems to a root. The matter was referred to in the *Daily Mail* of June 10th and my name mentioned as a grower of belladonna, in consequence I have received many hundred specimens for identification, only about 1 per cent of which were belladonna, and nearly all the remainder the woody nightshade. We have not nearly sufficient belladonna in this country for our national requirements, but with foxglove the case is different—there is abundant—but frequently growing in remote districts making the picking and transport to manufacturers difficult. Systematic cultivation of both these plants will greatly lessen the cost and at the same time make us independent of foreign supplies.

I am, Sir, yours faithfully,

J BEETHAM WILSON

95 High street, Dorking July 6th 1916

* * Our note, of course referred to the official plant, which is a widely distributed wild plant on the chalk soils of the east and south of the country. We are aware that the public almost to a man believes that *Solanum dulcamara* is the belladonna of the Pharmacopœia. In referring to belladonna as "a weed" we did not mean to imply that it was very common, but that where it occurred it grew without cultivation.—ED L.

"PIRATE" DOCTORS

To the Editor of THE LANCET

SIR,—Permit me to correct a few inaccuracies in your correspondent's letter of July 1st headed "'Pirate' Doctors," in which I am personally accused of attacking doctors for demanding what he alleges are reasonable fees. This is the direct opposite to what my letter of June 12th states. I there stated that, thanks to the loyal help afforded by the majority of those acting as locums, the demand had been so far met at reasonable fees and that the demands of the very small minority, with whom your correspondent associates himself, could soon be stopped by refusing to pay their demands.

Surely in such times as the present no one with any patriotism would for a moment suggest that the time is ripe for the profession to raise their fees by the 150 per cent your correspondent hints at. I have yet to learn that those who have so nobly given up their practices and joined the Royal Army Medical Corps to help their suffering fellow countrymen are receiving as he alleges, £2 or £4 per day. In my ignorance I understood the remuneration was usually 2s a day or about the same as paid to a locum tenens, except that the latter has no outgoings to pay and runs no risks. May I also remind your correspondent that within my recollection locum tenens' fees were £2 2s to £3 3s a week and therefore the present fee of £7 7s which he considers inadequate is an increase of over 200 per cent.

Once again may I thank the large majority of locum tenens and others who are loyally trying to keep together the practices of those who have joined the Royal Army Medical Corps.—I am Sir yours faithfully,

FREDRICK TURNER.

A lam street Adelphi W C July 11th 1916

CHILDREN'S HOSPITAL FOR WOMEN.—The new buildings of the Chelsea Hospital for Women in Arthur street were formally opened by the Queen on Tuesday last. The hospital was established in 1871 on the Fulham road and its useful work has long been hampered by inadequate accommodation especially in the out-patient department. There were formerly 50 beds for in-patients and accommodation is now to be provided for 80. A sum of £30,000 is still required to complete the building scheme.

The War.

THE CASUALTY LIST

THE following names of medical officers appear among the casualties announced since our last issue —

Killed

Captain H C Mulhern, R A M C, received his medical education at St Mary's Hospital, London, and qualified in 1905. When war broke out he was a surgeon at the Kingston Barracks Military Hospital, and joined the R A M C in December, 1914.
Lieutenant D Rodger, R A M C, qualified in 1907 at Manchester, and took the F R C S Edin in 1912. Proceeding to Australia he became Ophthalmic Inspector of Schools to the Queensland Government and relinquished the appointment to take up war work, joining the R A M C in December 1915.

Died of Wounds

Lieutenant E C Lambert, R A M C, attached to the East Surrey Regiment, received his medical education at Westminster Hospital, and qualified in 1898. He had held appointments at Banstead, Darenth, and Hanwell Asylums, and prior to joining the R A M C in December 1915, was assistant medical officer at Wandsworth workhouse.

Died

Lieutenant Colonel C Monk, I M S, qualified in 1874, and was for some time surgeon at the Military Hospital, Seintya. He was in retirement when the war broke out, and died after an operation at the 2nd London General Hospital, of which he was lieutenant-colonel in charge.
Captain A Seabrooke, R A M C, was educated at Cambridge and at Guy's Hospital, qualifying in 1912, and was in practice in Grays, Essex, before joining the R A M C.

Wounded

Lieutenant A C Taylor, R A M C
Captain H B Goulding, R A M C, attached to the Seaforth Highlanders
Lieutenant P H Macdonald, R A M C, attached to the Sherwood Foresters
Captain A Hamilton, R A M C, attached to the West Yorks Regiment
Captain W K A Richards, R A M C
Captain J H Glover, R A M C
Captain J H Tomlinson, R A M C
Captain R Dearsley, New Zealand Medical Corps
Captain G D Fairley, R A M C, attached to the Royal Scots Fusiliers
Lieutenant J R Hall, R A M C
Lieutenant J K Muir, R A M C, attached to the Northumberland Fusiliers

Missing believed Killed

Captain J L Green, R A M C, attached to the Sherwood Foresters
Previously Reported believed taken Prisoners at Ant el Amara, now reported not Prisoners of War

Captain F H Salisbury, I M S

THE NAVAL BATTLE OF JUTLAND, MAY 31ST, 1916

In the despatch received from Admiral Sir John Jellicoe Commander in Chief of the Grand Fleet, and the subsidiary despatch of Vice Admiral Sir David Beatty, the following references to medical operations occur —

The work of the medical officers of the Fleet, carried out very largely under the most difficult conditions, was entirely admirable and invaluable. Lacking in many cases all the essentials for performing critical operations and with their staff seriously depleted by casualties they worked untiringly and with the greatest success. To them we owe a deep debt of gratitude.

Exceptional skill was displayed by the medical officers of the Fleet. They performed operations and tended the wounded under conditions of extreme difficulty. In some cases their staff was seriously depleted by casualties, and the inevitable lack of such essentials as adequate light, hot water, &c. in ships damaged by shell fire tried their skill, resource and physical endurance to the utmost.

HUDDERSFIELD WAR HOSPITAL MAGAZINE —

This is an addition to the journals published by several of our war hospitals and like its contemporaries will devote its profits to extra comforts for the sick and wounded. Among the contents of No 1 the July issue is the first instalment of extracts taken from a diary recording the story of the retreat from Mons. Visier E G Coward is the editor, and the price is 2d monthly.

THE INFECTIOUS CONDITION OF PATIENTS DESQUAMATING AFTER SCARLET FEVER

To the Editor of THE LANCET

SIR,—Dr Donald W O Hood in your issue of July 1st relates an interesting instance which points to the probability of an officer with desquamating feet having infected other officers occupying beds in the same ward. Dr Hood apparently jumps to the conclusion that, granted the fact of infection, this was due to the desquamation. It is more probable, however, that it was due to infectious particles discharged from the nose or throat. Every medical officer of health knows of many cases of scarlet fever which appear to be infectious long after desquamation as well as all other pathological conditions have ceased. When this occurs with diphtheria we are commonly able to detect diphtheria bacilli in the throat or nose. We have not got the advantage of bacteriological diagnosis for scarlet fever, but analogy would indicate that the source of infection is the same as it is proved to be in diphtheria—viz the naso-pharynx.

I am, Sir, yours faithfully,

SIDNEY DAVIES,

Medical Officer of Health

Public Health Department Town Hall Woolwich
July 10th, 1916

FAT-HEADEDNESS

To the Editor of THE LANCET

SIR,—The letter of the Director of the Westminster Hospital Laboratory published in your issue of July 1st points a valuable moral and well illustrates the prevalent neglect of science and want of co-ordinated intelligence in authoritative headquarters. Laboratory assistants engaged in the work indicated by Dr R G Hebb are not trained in a day, and it is well known that medical assistants in any branch of work are scarcely to be found at the present time. It is needless to insist on the necessity of a pathological laboratory as an integral part of an up-to-date hospital, the average layman knows this quite well. But some in authority seem to think that there is virtue in a laboratory without workers, just as others responsible for the National Insurance Act seemed, at least at first to be of opinion that adequate medical attendance consisted in a momentary interview and a bottle of physic.

Dr Hebb supposes that there is no use in appealing. But it seems to me that if the governing body of Westminster Hospital were to appeal to the Army medical authorities a possible cure for this particular case of official lipocephaloma might easily be achieved.—I am, Sir, yours faithfully,

London July 6th 1916

H BRYAN DOWKIN

To the Editor of THE LANCET

SIR,—Dr R G Hebb, in his letter which appears in your issue of July 1st, does not mention by whom the application for the exemption of his laboratory assistants was made. If it was made by himself and was in a tone approaching that of his letter can it be wondered at that it was refused?

An application was made on behalf of a similar official at the hospital which I write from and on appearing before the tribunal we were treated most reasonably and courteously. We did not get all we asked but we should certainly not characterise as a "fat-headed committee" a body of gentle men who did not see eye to eye with us but who are doing their duty to their country (and a very difficult duty) as well as Dr Hebb himself.—I am, Sir, yours faithfully

July 5th 1916

HOSPITAL SUPERINTENDENT

WOMEN STUDENTS AT THE LONDON HOSPITALS

To the Editor of THE LANCET

SIR,—Sir John Broadbent's letter in your issue of to-day demands a word of explanation from me. I only mentioned St George's Hospital as having admitted women students to its wards because that hospital was the only one of the four hospitals with which we at King's College are associated which had taken this step up to the date of my letter. I was dealing with the matter solely from the point of view of providing clinical instruction for women students who take their

preliminary and intermediate work with us. I was quite aware that St Mary's Hospital had thrown open its doors to women students, and I understood from a letter which Sir John Broadbent wrote to me about a month ago that his agreement with the London School of Medicine for Women precluded him from taking women medical students from any other source. From the King's College standpoint therefore, St Mary's Hospital was of no use to us and that is the simple reason why I omitted to mention their recent action.

I am, Sir, yours faithfully,

W D HALLIBURTON,

Dean of Medical Science Faculty King's College London

July 8th, 1916

THE SHOCKLESS OPERATION

To the Editor of THE LANCET

SIR—I have read with great interest Mr P Lockhart Mummery's article with the above title in your issue of July 1st and only wish he had been present in 1914 at the discussion on "Anoci Association" at the annual meeting of the British Medical Association, when Colonel H M W Gray had a very hostile audience to face until his subsequent demonstration in his theatre at the Aberdeen Infirmary. Having used Colonel Gray's technique for the past four or five years and seen a good deal of his own work, I would like to touch on a few points which may prove interesting to Mr Lockhart Mummery and others who are following Crile's methods.

As regards the preliminary narcotic, I find that omopon and scopolamine or alupon and scopolamine, the latter an Allen and Hanburys' preparation, are preferable to morphia and scopolamine—the former give a quieter sleep with much less headache and morphia squeamishness afterwards. The use of nitrous oxide or any inhalation anæsthetic is unnecessary if the preliminary narcotic is given in suitable dose and the system of local anæsthesia is perfect. One cannot be sure of having blocked all nociceptors if the patient is "quite unconscious," although a skilled anæsthetist might observe "signs of stimulation." Another objection to nitrous oxide and oxygen analgesia is the risk of considerable struggling, this, of course, is not very frequent but might prove very dangerous after the abdomen was opened, and I have it on the authority of a very skilled administrator of nitrous oxide that this struggling is by no means uncommon. Personally I have managed appendicectomies, gastro-enterostomies, prostatectomies, cholecystostomies, cholecystectomies, ovariectomies, and amputation through thigh and leg without any inhalation anæsthetic, but find it advisable to give a very little open ether along with the regional anæsthesia and narcotic in hysterectomies, big resections of bowel, and in renal operations. If we inject novocaine solution well to the side of the abdomen between the ribs and ilium we get a vastly improved abdominal relaxation which permits of far more easy exploration of the abdomen, and consequently much less need of a general anæsthetic.

For the semi isolated general practitioner doing surgery these methods are of great value but have to be seen to be understood and require a considerable amount of practice and the use of nitrous oxide and oxygen is rather a bar to their more universal adoption. I must add a warning word about chloroform which Mr Lockhart Mummery says may be given—one has to use a certain amount of adrenalin with the novocaine, and I have seen one or two cases where I could not help thinking that the combination of adrenalin and chloroform had dangerous results—it may not be so but others have had the same experience as myself. Colonel Gray's technique of injection is very different from that advised by Crile and Lower in their work on the subject and by allowing more time to elapse between the preparation and the attack achieved by infiltrating all layers of the abdominal wall prior to using a knife at all seems to me to be a sounder method though more difficult to achieve proficiency in. I have no doubt that had Colonel Gray been a civil practitioner we would have had by this time a very interesting résumé of his experience in this work on our bookshelves and we must remember that he was the pioneer of 'The Shockless Operation' in this country, and was working on these lines while many of us were students in his ward.

I am, Sir, yours faithfully

Coward is the editor, and the price is 2d. monthly.

OBITUARY OF THE WAR

JOHN GLADSTONE MACKENZIE, M B, CH B GLASG,
CAPTAIN, AUSTRALIAN ARMY MEDICAL CORPS

Captain J G Mackenzie, who was killed on active service in France on May 21st, was the son of Mr John Mackenzie, formerly resident in Lanarkshire, Scotland, and now in

Victoria, Australia. He graduated in medicine at Glasgow University in 1910 and then settled in practice at Wonthaggi, in Victoria, where, his brother tells us, he became an extremely popular practitioner. In August, 1915, he joined the Australian Army Medical Corps, becoming attached to the 8th Field Ambulance and was transferred later to another section in France. He was killed by a shell which exploded at his feet near to his dressing station, and

death was practically instantaneous. His commanding officer writes of Captain Mackenzie that he had "proved himself a very efficient soldier and an unusually well qualified medical officer also," adding that his name "had appeared on the day of his death in Orders as being detailed for special instructional duties regarding protection against asphyxiating gases."

DOUGLAS WATERSTON, B A., M D., C M MCGILL,
CAPTAIN, CANADIAN ARMY MEDICAL CORPS

Captain D Waterston, of the Canadian Field Ambulance, O E F, who was killed in action in Flanders on May 22nd was the youngest son of Mr and Mrs Thomas Waterston, of Montreal, Quebec, and was born at Belleville Ontario Canada on June 18th, 1889. He was educated at Belleville High School, and entered McGill University in 1905, taking

his B A in 1909 with first-class honours in biology and his degree in medicine in 1914. During his course in arts he contracted tuberculosis and spent parts of 1909 and 1910 at Saranac Lake, New York State, where he happily made a good recovery. After graduation he was appointed interne to the Montreal General Hospital holding this position until January, 1916 when he entered the Army Medical Service as Captain in a Canadian

Field Ambulance then being raised in Montreal. While on the resident staff of the hospital he qualified for a commission in the C A M C and received leave of absence to act as medical officer to the Mobilisation Camp at Three Rivers Quebec during the summer of 1915.

We learn from one of the physicians to the Montreal General Hospital that Captain Waterston was held in high esteem by his associates and by the visiting staff of the hospital. In entering his country's service he gave up the prospect of a brilliant career. He is the first medical officer from Montreal to make the great sacrifice during this war.

FREDERICK ALBERT CAPPS, L R C P Edin.,

FLEET SURGEON ROYAL NAVY

Fleet-Surgeon F A Capps, who was the senior medical officer on H M S *Defence* when sunk with all hands in the naval battle on May 31st was 50 years of age. He was educated at Plymouth and Edinburgh, taking his medical qualification in 1890, and obtaining 22 years later the diploma of D P H with honours at the University of Ireland. After a short period of private practice he entered the Navy in 1892 and saw varied service on the Australian station and at Gibraltar. On promotion to staff surgeon in 1900 he was appointed to Haslar for the second time, and was later in medical charge of the training ship *Black Prince* and at the *Mercury* submarine depot. It was while here that he gained special experience in submarine life saving apparatus and himself contributed some valuable inventions. He was promoted fleet-surgeon in 1908.

Fleet-Surgeon R O Munday, editor of the *Royal Naval Medical Journal*, to whom we are indebted for part of this account of his friend writes of him "It was characteristic of this officer that whatever his hand found to do was carried out with energy and industry. He never spared himself in his professional work yet he found time to become a very clever carpenter and was a good tennis player."

DEATHS AMONG THE SONS OF MEDICAL MEN

The following sons of medical men must be added to our lists of those who have fallen during the war —

- Second Lieutenant H C Dalby, York and Lancaster Regiment eldest son of Major H E Dalby, R A M C of St Mary Church, Torquay.
- Captain R S Sweetnam, Royal Field Artillery, only child of Deputy Inspector General J L Sweetnam, R N of Worthing.
- Lieutenant R T Twining, Devonshire Regiment only son of Dr D O Twining of Salcombe South Devon.
- Captain W J Davis Northumberland Fusiliers second son of the late Dr R Davis, of Orpington Kent.
- Lieutenant K R Traill, Royal Berkshire Regiment younger son of Dr C G Traill of Sunningdale Berks.
- Lieutenant C Vaisey Royal Flying Corps, eldest son of Dr T F Vaisey, of Winslow Bucks.
- Second Lieutenant C V Beddow Devonshire Regiment second son of Dr J Beddow, of Thorverton Devon.
- Second Lieutenant J R L Hunt Sherwood Foresters only son of Dr J A Hunt, of Borrowash Derbyshire.
- Second Lieutenant J F Baddeley, The Buffs son of the late Dr C F Baddeley of Belvedere Kent.
- Lieutenant F G V Beard Worcestershire Regiment, eldest son of Dr F Beard, of Croxson Surrey.
- Lieutenant Colonel G A Royston Pigott DSO Northamptonshire Regiment eldest son of the late Dr G W Royston Pigott F R S.
- Second Lieutenant W Harrison Gordon Highlanders only son of Dr J Harrison of Ilesmahagow Lanarkshire.
- Colonel H C Bernard Indian Army attached to the Royal Irish Rifles only surviving son of the late Dr P Bernard Deputy General Inspector of Hospitals and Fleet and Honorary Surgeon to the Queen.
- Lieutenant D Rolger R A M C younger son of Dr P Rodger West Kirby, Cheshire.
- Second Lieutenant A C Brown South Staffords only son of the late Dr J Brown of Tring Herts.
- Lieutenant (temporary Captain) A Holbourn Leicestershire Regiment youngest son of Dr Holbourn of Farnham.
- A Rieu Middlesex Regiment fourth son of the late Dr C Rieu of Woburn square London.
- Second Lieutenant J C M Stewart Royal Field Artillery eldest son of Dr J Stewart of Leeds.

Bristol W H Cellier Guy's Hospital, K R Chapple St Bartholomew's Hospital, B I H Christmas Middlesex Hospital, D A Dyer Kings College Hospital, W F Gawne Liverpool, J Gordon Leeds, W S Hazell Bristol, A M Horsey Cambridge, G Hume Guy's Hospital, H Jennings Liverpool, F C Jones Manchester, A H Kettlewell Bristol, G Massie and W W Payne Guy's Hospital, B W Roffey St Mary's Hospital, C H St John Guy's Hospital, and J A P Shaw Cambridge.

PRIMARY EXAMINATION PART I

Biology—M Fox Royal Free Hospital, A H Kettlewell Bristol, and G R A de M Rudolf King's College.
Chemistry—M Fox Royal Free Hospital, F Lyth H Lyth and J A Marriott Manchester, G R A de M Rudolf King's College, and G A P Wright Bristol.
Veterin Medicine and Pharmacy—S Robinson Belfast and F A. Unwin King's College Hospital.

UNIVERSITY OF GLASGOW—The following candidates have passed the examination for the degrees of Bachelor of Medicine (M B) and Bachelor of Surgery (Ch B) in the subjects indicated—B, botany, P, physics—

Gavin Hadow Boyd (B) William Brock (P) Joseph Dewar (B P) William Norman Duguid (B) Bruce Paterson Gardner (P) Thomas Gibson (B P) Charles Glen (B P) James Lorimer Halliday* (B P) David Russell Hamilton (B P) George Harvey (B P) Wesley Cope Houldsworth (B P) William Livingstone Kennedy (B P) William Martin MacCash (B P) Thomas Simpson MacDonald (B P) Robert Kennedy M Dougall (P) James M Nair (B P) William Muir (B P) George William Murray* (B P) James Nairne (B P) Malcolm Nicolson (B P) Alexander Hunter Rankin (B P) Thomas Gilliland Rankine (B P) Donald Stewart (Partick) (B P) Alexander Symon (B P) Andrew Smith Taylor (B) Charles Noel Temple (B P) George Tudhope (B P) John Wyllie (B) and John Yule (B P).

* Distinction in Physics

UNIVERSITY OF ABERDEEN—The following degrees were conferred at the recent Graduation ceremony—

DEGREE OF DOCTOR OF MEDICINE (M D)

James Watt George Byres, and Alexander William Overbeck Wright

DEGREES OF BACHELOR OF MEDICINE (M B) AND BACHELOR OF SURGERY (Ch B)

Robert James Clark *William Corner (second-class honours) Alexander Henderson Craig George Stewart Davidson George Ewen Andrew Fowler Douglas Morrison Milne Fraser Alexander Johnston Gordon James Key Douglas Lyon Alastair Cameron MacDonald (second-class honours) George Strathdee Mather John Archibald Nicholson Alexander Keith Robb Douglas Somerville Scott Robert John Smith George Thomson, and William Duke Whamond

* Passed Fourth Professional Examination with much distinction
 † Passed Fourth Professional Examination with distinction

The John Murray Medal and Scholarship and the Lyon Prize were awarded to Dr Arthur George Reid

METROPOLITAN HOSPITAL SUNDAY FUND—The following are among the amounts received at the Mansion House up to July 11th—

St Marks North Audley street £1402 St Columba, Pont street £491 St Paul's Knightsbridge £304 Holy Trinity Sloane-street £370 Essex Church Kensington £246 St Peter's Cranley gardens £166 St Mary in the Boltons £169 St Marks Hamilton terrace £141 Holy Trinity Tulse-hill £139 Greek Church Bayswater £133 St Stephen's Gloucester road £135 St Paul's Onslow-square £130 Emmanuel Wimbledon £123 Christ Church Gipsy hill £118 St Stephens South Dulwich £117 St John's Presbyterian Church Forest Hill £111 St John's, Penge £110 St John's Bromley £103; Mr J A Roberts £100 St John's Presbyterian Church Kensington and St Marks Regate £93 each St Peter's Bayswater £91 St Philip's Kensington £66 St Michael's Blackheath £53 Westminster Abbey £79 All Saints Ennismore-gardens £78; St Anna's Wandsworth £76 Highgate Presbyterian Church £74 St Luke's Hampstead £71 St James's Piccadilly £70 Christ Church Lee £68 Chipping Barnet Parish Church St John's Putney and All Saints Highgate £62 each Hornchurch Parish Church and Regent's Park Chapel £60 each St John's Notting hill and St Nicholas, Chislehurst £57 each Christ Church Beckenham St James's West Hampstead and St Marks Marylebone-road £56 each St James's Kidbrook £55 Union Chapel Islington £53 Messrs J H Vasseour and Co £52 10s and Kensington Congregational Church and Mr Norman McCorquodale £20 each.

The total available for distribution to date amounts to about £45 5/0

ANNUAL PROVINCIAL MEETING OF THE SOCIETY OF MEDICAL OFFICERS OF HEALTH—The annual provincial meeting of this society took place on July 1st at Hampton Court when a large number of members attended from all parts of the country. Among those present were the President (Dr Francis J Allan, medical officer of health of the city of Westminster), Dr John Robertson medical officer of health of Birmingham (President-elect of the society for session 1916-17) Dr C W F Young county medical officer of health of Middlesex, Mr H Beale Collins (Kingston) and Dr B C Stevens (Mortlake). A business meeting was held in the forenoon, after which a visit was paid to some of the works of the Metropolitan Water Board under the guidance of Alderman R Woolley Walden J P chairman of the Water Examination Committee, Dr A C Houston Director of Water Examinations, and Mr W B Warburton S'ent A M I C E resident engineer at Hampton. Dr Allan,

in proposing a vote of thanks to the Water Board referred to the vast improvements which had been effected. Fifty years ago London obtained its water from the Thames between London Bridge and Chelsea, and he remarked that an old guide book to London of the year 1856 described that part of the river as being at once our cistern and our sewer.

MEDICO PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND—The annual meeting of this association will be held on July 27th at 11, Chandos street, Cavendish square, W, at 2.45 P M, when the following papers will be read "Mental Disabilities for War Service" by Sir George Savage, and "Functional Gastric Disturbance in the Soldier," by Captain Colin McDowall, R A M C

WOMEN MEDICAL STUDENTS AT CHARING CROSS HOSPITAL—We are informed by the Dean of Charing Cross Hospital Medical School that the council of the hospital have decided to admit women students to the medical school and hospital as a temporary measure. They will be admitted on the same terms as men students and can enter either for the full course or for the final studies only.

SPHAGNUM MOSS—At the last meeting of the Devon Education Committee a letter was read from the Devon Voluntary Aid Organisation asking that school children might be encouraged to gather sphagnum moss to be used as dressings for wounds. It was stated that a large quantity was required as quickly as possible. The committee decided to communicate with the local school authorities upon the subject.

EDINBURGH ROYAL INFIRMARY—At a meeting of the managers of the Edinburgh Royal Infirmary held on July 3rd the following appointments were made—Resident physician Ernest O A Singer (final year student) to Professor Sir T R Fraser (for three months) Resident surgeon Ronald N MacKenzie (fourth year student) to Mr A A Scot Skirving (for six months) Clinical assistant Stanley E Crawford, M D (Pennsylvania University, U S A) to Dr Norman Walker (for six months)

EUGENICS EDUCATION SOCIETY—The Eugenics Education Society has been devoting considerable attention to the question of reducing the present penalisation of parenthood. At the general council meeting held on July 6th at the Grafton Galleries the following resolutions were unanimously adopted, and will be brought to the notice of those in authority—

1 That it is desirable without affecting the total amount raised by income-tax from the nation to make changes in the incidence of the tax in order to decrease much further than has yet been done the heavy burden on parents with dependent children.

2 That the best way of securing this adjustment would be to assess the total income of a family as a number of separate incomes the number bearing some relation to the number of persons the income has to support.

3 That the Executive Committee be empowered to take such steps as may seem advisable to bring this resolution to the notice of the Government.

Major Leonard Darwin, in his presidential address to the society, said that in the rebuilding of the nation after the war it will be far more important to strive to maintain the quality of the people than merely to increase their number. A general increase in the population has already been advocated to fill the gaps made by the war whilst the poverty expected after the war has been made an argument for a decrease in the birth rate. The density of the population results from a balancing of two opposing forces—the desire for marriage and the fear of the cost of maintaining a family. As to why different grades of society the obvious established in the different grades of society the obvious reason is that differences of wealth arise by chance and are maintained by the inheritance of property. But there is another explanation. Men of exceptional natural abilities are constantly being selected out of the poorer ranks whilst vast numbers constantly keep falling down into them. The natural qualities leading to success pass on from generation to generation and differences in the standard of living thus tend to be maintained. The principal cause of the lower fertility associated with greater wealth is that as prosperity increases so do the pleasures which compete with marriage. The efforts now made however aim at a transfer of wealth to the poor as a class and not to the individual, and such efforts are likely to increase the rate of multiplication of the classes affected. We have no right to assume that the existing high fertility of those at the bottom of the social ladder will not increase in future. No one is striving to weed out the unfit into a class apart or to make them multiply rapidly but this is the direction in which we now seem to be moving. If so there exists a growing cancer in the body of the nation which ought to be cut out at all hazards. Steps taken to increase the population are likely to be condemned as adding to the misery of the poor. But such fears must not prevent us from advocating an increase in the rate of reproduction amongst the fit.

Obituary.

PAUL H RÖMER, M D MARBURG

Paul Römer died on March 30th of typhus contracted on the Eastern front in his fortieth year. A native of Marburg, he spent most of his school and academic life there, and was one of von Behring's most trusted pupils. His work was constant and of a very high order, and his numerous contributions to medical literature are all distinguished by the same thoroughness and exactness, the same clarity of aim and expression. In this country Römer was best known as the author of a monograph on Epidemic Infantile Paralysis which has appeared in translation,¹ and which is a model of what a monograph should be. In tuberculosis his work went far towards firmly establishing the thesis that the majority of the human race by means of repeated small infections in childhood acquires such an immunity that tuberculous infection of an adult from without becomes a rarity. His friend, Hans Much, testifies² that Römer's life was as upright as his research work. Both were of a type which will be sadly missed.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

The Reports of Certifying Surgeons

Clause 8 of the Police &c (Miscellaneous Provisions) Bill deals with the abolition of investigations of accidents by certifying surgeons. As amended in Committee by the House of Commons on Thursday, July 6th it runs thus: "1. After the expiration of one month from the passing of this Act it shall cease to be the duty of certifying surgeons to investigate the nature and cause of death or injury caused by accidents in factories and workshops or in premises to which the provisions of the Factory and Workshop Acts, 1901 to 1911, relating to accidents, are applied, or to send to the Inspector of the district reports thereof, provided that nothing in this section shall affect Subsection (3) of Section 73 of the Factory and Workshop Act, 1901 relating to the investigation by certifying surgeons of diseases occurring in factories and workshops. Provided also that it shall continue to be the duty of the certifying surgeon to investigate and report upon cases of injury caused by exposure to gas, fumes, or other noxious substances, or due to any other special cause specified in instructions of the Secretary of State as requiring investigation. It shall also be the duty of the certifying surgeon to investigate and report upon any case of injury which the district inspector of a factory in pursuance of any general or special instructions from the Secretary of State may refer to him for that purpose and the Secretary of State shall issue instructions defining the causes of injury to which this provision is to apply and requiring the inspector of the district to refer to the certifying surgeon all such cases reported to him. The certifying surgeon shall have, for the purpose of the investigation in any such case, the same powers and shall be entitled to receive the same fee as he would if the case had been a case to which Section 73 applies. 2. As from the same date the enactments mentioned in the Schedule to this Act shall be repealed to the extent mentioned in the Schedule to this Act."

The presence of the original clause in the Bill led to a very considerable debate on the second reading. The Home Secretary was then urged by a considerable number of Members to consent to the deletion of the clause, and he promised to bring forward an amendment to modify its provisions. That amendment has been introduced into the clause as set out above. It begins: "Provided also that it shall continue to be the duty of the certifying surgeon" and extends down to "the same fee as he would if the case had been a case to which Section 73 applies." The ground covered by the discussion ranging round this amendment was in the main that covered in the debate on the second reading. A very considerable objection was taken to the clause, particularly as it stood in its original form.

Sir P. MURPHY, during the debate in Committee, said that the saving in money which the clause would bring about would only be £5000 or £6000 and it was not worth while to insert it in the Bill. He criticised the qualifications of inspectors of factories and said that it was the certifying

surgeon who alone possessed the scientific knowledge to judge questions relating to machinery and to mechanical, physical, and even chemical processes. It would be disastrous to the interests of the workpeople that the report should depend on the inspector only without the advantage of the consideration given by the certifying surgeon.

Mr TYSON WILSON advocated dropping the whole clause. The workpeople who would be affected believed that the abolition of the certifying surgeons' reports would affect them prejudicially.

Sir ROBERT FINLAY considered that it would be better to leave it to the discretion of the certifying surgeon as to what cases required a medical report. Of course, if there were inspectors qualified by scientific knowledge to discharge the duties which were now discharged by the inspectors jointly with the certifying surgeons the evil might be mitigated, but it was very undesirable to abolish the reports of the certifying surgeons.

Mr HERBERT SAMUEL (the Home Secretary) remarked that what had occurred did lead him a little bit to suspect that behind the scenes there must have been acting the very powerful organisation of the doctors which honourable Members knew was always ready to take active steps whenever their interests were in any way affected. The report of the Accidents Committee showed that the portion of the certifying surgeons' work which it was proposed to abolish was superfluous, and that the reports in effect were duplicates. All the factory inspectors were experts in mechanical safety appliances. The certifying surgeon did not treat the injured workman. He was not the man who examined him and diagnosed his case. His work was to see the workman and send in one of those reports which were, as a rule, entirely useless. The certifying surgeon had no power to take any action. The Bill did not propose the abolition of the certifying surgeon. The certifying surgeon would still continue to perform his most useful function of examining all young persons and children who were to enter a mill.

Several honourable Members asked the Home Secretary to drop the clause. Ultimately the right honourable gentleman's amendment in the form set out above was agreed to, and on a division the clause as amended was carried.

The Bill was read a third time by the House of Commons.

Cabinet Changes

Several changes in the Cabinet are announced. Mr LLOYD GEORGE has become Secretary for War. His place as Minister of Munitions has been taken by Mr MONTAGU MR McKINNON WOOD becomes Financial Secretary to the Treasury, and Mr TENNANT succeeds him as Secretary for Scotland.

HOUSE OF COMMONS

WEDNESDAY, JULY 5TH

Medical Arrangements in Mesopotamia

Sir HENRY CRAIK asked the Secretary for India whether the report of Sir W. Vincent and General Bingley upon the medical arrangements in connexion with the Mesopotamia expedition had yet been received, and, if so when it would be published. Mr CHAMBERLAIN replied: "The report has not yet been received."

Mr ANNAN BRYCE asked the right honourable gentleman whether the sum of at least 16 lakhs of rupees was put by princes and other wealthy persons in India at the disposal of the Government of India for the purpose of a proper medical equipment of the expedition to Mesopotamia, if so, what portion of that sum was applied to such equipment, and what department or officer of the Indian Government was responsible for the expenditure or non-expenditure of the money. Mr CHAMBERLAIN answered: "No such gift has been reported to me by the Government of India. Several Indian chiefs combined to present a hospital ship for the general purposes of the war, and some motor ambulances, motor-cars, and the like have been presented by individual donors or by communities for the troops in Mesopotamia."

Inspectors of Factories

Sir P. MAGNUS asked the Under Secretary for the Home Department what steps had been taken to give effect to the recommendations of the Committee on Accidents in Factories as to the examination to be passed by applicants for inspectorships and whether nominations for the inspectorate were now limited to the classes of persons suggested in the report. Mr BRUCE replied: "The revision of the scheme of examination and conditions of nomination was being considered in consultation with the Civil Service Commissioners at the outbreak of war, and has had to be suspended for the time being. Meanwhile no fresh appointments to the permanent staff are being made."

The Health of Women Workers

Mr HASLAM asked the Parliamentary Secretary to the Ministry of Munitions whether he was aware that where women worked the 8 hour shift system with 30 or 40 minutes interval within the eight hours for refreshment it

¹ *Epidemic Infantile Paralysis*. Translated by H. Ridley Penrice. M.P. Laid on the Table Sept. 1, 1913.

saw that he had been able to adopt, to a very large extent at all events, the recommendations of the Commission. He desired to pay a tribute of gratitude on behalf of the Government and the House of Commons to the Commission for the splendid work which it had done. There were no diseases which had done more injury to the life of the people and more destroyed their soundness than had venereal diseases. Their consequences were terrible because these affected the succeeding generation. Nothing was more horrible than to see little children who had inherited venereal disease. He believed that if the recommendations of the Commission were followed consistently in the country a measure of relief would be given. The Commission had suggested that there should be facilities for diagnosis and treatment, that there should be available for the whole population, that they should be free of access, and it was recommended that if the work was done through the local authorities 75 per cent of the cost should be found by the State. The Chancellor of the Exchequer had agreed that that grant should be given. An announcement was made by him (Mr. Long) to that effect, and schemes were coming into existence. The counties and county boroughs were organising facilities in connexion with institutions. The Local Government Board was issuing an Order, of which he had approved the other day, imposing this duty upon local authorities. The measures which the Board was calling upon them to take were—(1) that there should be laboratory facilities for free diagnosis, (2) that there should be clinics at the general hospitals for treatment, and (3) that there should be a gratuitous supply of the great remedy, salvarsan. He had seen in one of the London hospitals a ward set apart for the treatment of venereal disease and he earnestly hoped that all the great hospitals in the country would give their immediate aid in this work. He knew that some of those responsible for hospitals entertained a fear lest the importation into their institutions of the treatment of this disease would injure the reputations of the hospitals. It would do nothing of the kind. It was only possible to deal with this fell disease satisfactorily if the provision was universal. If patients had to go long distances in order to get hospital accommodation he was afraid that they would not go, and the remedies would not be available for them. He was quite confident that there was no reason to fear that by offering facilities for the treatment of this disease any hospital in the country would suffer in credit or in the good opinion of those who supported it.

Appeal for Public Co-operation

He invited the co-operation of local authorities, hospital authorities, medical men and the public generally. He hoped that there might also be co-operation on the part of ministers of religion throughout the country who could do a great deal to help in this beneficent work. Naturally there was a feature attached to this disease which did not belong to ordinary troubles. The patient did not like it to be known that he or she was suffering from it. Patients wanted to conceal the fact. Therefore if they were to be dealt with great care must be taken not only that there was proper provision for their treatment, but that everything that could be done was done to enable them to get it without unnecessary identification. One of the conditions which he had endeavoured to establish in consequence of this was that it should not be considered essential that a person coming to a hospital for treatment should belong to the district which the hospital served. He was requesting that questions should not be asked so as to identify the patients outside with the terrible misfortune that had overtaken them. It was desired to cure them and to eradicate this horrible disease. It could be done. If the Government received the assistance of people of all classes he believed that the time was not very far distant when this disease might be added to those the permanent ill-effects of which had been eradicated by satisfactory treatment.

Sanatoriums

Although there was a shortage of medical men there were to be 200 sanatoriums and hospitals and 11,743 beds which had been provided for the treatment of tuberculosis in England. There had also been 359 dispensaries provided and there was today sufficient accommodation for our present demands. All soldiers and sailors suffering from tuberculosis could be provided for by those institutions. Many of the men were insured persons and arrangements in their case were made through the Insurance Committees. But there were many soldiers and sailors who were not insured and for them arrangements were made by the Local Government Board through the local authorities. There were also special arrangements for the treatment of officers. The Hon. Edward VII. Sanatorium at Aldhurst. The fact was allowing for a normal work in connexion with the health of the nation although it was embarrassing in many fields of enterprise. It was impossible to exaggerate the importance of the work and of protecting women

and children from the mortality which followed from preventable diseases. Some of those diseases, if they were not actually traceable to, were undoubtedly aided and abetted by overcrowding, insanitary conditions in the homes, and by many of those social evils which had existed through so many generations and of which he was sorry to say the solution was not yet in sight. The Board had done its best to maintain the sanitary services. On the whole the record which he was able to present was not unsatisfactory.

Tribute to the Medical Profession

After the war there were many problems which would present themselves for immediate solution—the housing of the people, public works, and further health provision. The Government had set up a Reconstruction Committee, and all these problems were under careful survey and examination. The nation must realise that the health of the people was a matter of first consideration. In some respects there was great room for improvement. Throughout the last year or two there had been an immense amount of voluntary work on the part of people of all classes. He desired to pay a special tribute to medical men throughout the country. Insurance work had thrown upon them an immense burden of work. A very large number of them had joined the Royal Army Medical Corps. That diminished the number available for work at home. Cheerfully and bravely had these men done their work. Let anyone examine the diary of their day's work and see what they were accomplishing. There was no grumbling. The nation owed a special debt of gratitude to these men who were labouring in order that the population might be kept in good health. None at home were doing more than they were at present.

In the debate which followed general satisfaction was expressed with the statement made by the President of the Local Government Board.

Appointments.

Successful applicants for vacancies Secretaries of Public Institutions and others possessing information suitable for this column are invited to forward to THE LANCET Office directed to the Sub-Editor not later than 9 o'clock on the Thursday morning of each week such information for gratuitous publication.

BARROW G. A. M.R.C.S. L.R.C.P. Lond. has been appointed Anesthetist to the Manchester Royal Eye Hospital.
BROOKLYN L. M.B. M.C. Cantab. F.R.C.S. Eng., Assistant Surgeon to Guy's Hospital.
CONSTABLE, EVELYN A. M.B. B.S. Durh., Surgical Registrar to the London Temperance Hospital.
DORN FORD A. C. L.S.A. Lond. Certifying Surgeon under the Factory and Workshop Acts for the Faringdon District of the county of Berks.
HACKETT J. A. W. M.B. Ch.B. Edin. Certifying Surgeon under the Factory and Workshop Acts for the Galusborough District of the county of Lincoln.
LLOYD J. T. M.R.C.S. L.R.C.P. Lond. Certifying Surgeon under the Factory and Workshop Acts for the Tregaron District of the county of Cardigan.
ECARBOROUGH HILDA M.B. B.S. Lond. Assistant Resident Medical Officer at Queen Charlotte's Lying-in Hospital.
THOMSON ROBERT BUSHEN, M.B. Ch.B. Vict. Manch. Acting Deputy Medical Officer of Health for the Brixham (Devon) Urban Council.
WOOD-BILL, NELSON F.R.C.S. Edin. M.R.C.S. L.R.C.P. Lond., Deputy Medical Officer of Health for Truro (Devon).

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see index). Where the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

BEDFORD COUNTY HOSPITAL.—House Surgeon unmarried Salary as arranged with board &c.
BIRMINGHAM AND MIDLAND EYE HOSPITAL, Church-street.—Resident Surgeon Salary £200 per annum with board &c.
BIRMINGHAM UNIVERSITY.—Lecturer in Physiological Department Salary £200 per annum.
BOLTON INFIRMARY AND DISPENSARY.—Female Second House Surgeon Salary £200 per annum with board &c.
BRISTON CITY B. BOLTON ISOLATION HOSPITAL.—Resident Medical Officer Salary £250 per annum with board &c.
BRISTOL GENERAL HOSPITAL.—House Physician Salary a rate of £175 per annum with board &c.
BRISTOL ROYAL INFIRMARY.—House Surgeons and House Physicians Salary at rate of £120 per annum with board &c.
BRISTON INFIRMARY.—Junior House Surgeon Salary £150 per annum with board &c.
CHESHIRE COUNTY BOROUGH ISLINGTON HOSPITAL.—Resident Medical Officer Salary at rate of £250 per annum with board &c.
FRIMLEY WAR HOSPITAL.—Resident Medical Officer Salary as arranged.
HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physician for six months Salary Surgeon &c.
HULL, VICTORIA HOSPITAL FOR SICK CHILDREN.—Female House Surgeon Salary £100 per annum with board &c.

was reported that better results both with regard to health and production, were obtained than under the 12 hour shift system whether there were now any industries under his control where women were allowed to work longer hours than were permitted under the Factory Acts, if so, would he immediately take steps to stop this practice, which was shown by the report of the health of munition workers to be detrimental to health and effective production, and whether all cases of overtime worked by women workers were reported to the Home Office and required the sanction of that department—Dr ADDISON said in reply It has generally been found that from the point of view of health a three shift system, where practicable, is preferable to a 12 hour shift system In a good many cases, however, the shortage of labour and difficulties of housing accommodation make a three shift system impracticable, and the system involves also certain difficulties of organisation On the other hand a two shift system where hours in each shift are not excessive is often quite satisfactory As regards the second part of the question, it has been decided in concurrence with the Home Office to bring the hours of work for women and young persons in controlled establishments generally within the weekly limit of 60 hours allowed under the ordinary provisions of the Factory Act, and steps are being taken to give effect to this decision Wherever an emergency necessitates any extension of hours the sanction of the Home Office is required

THURSDAY, JULY 6TH

Masseurs in Military Hospitals

Mr TYSON WILSON asked the Under Secretary for War whether he was aware that the members of the National Association of Trained Masseurs had made application for appointment as masseurs in military hospitals, and that although their qualifications were as good as those of persons who had been appointed their applications had been refused, and whether he would state why the War Office refused to avail itself of these fully trained masseurs—Mr TRENTON answered Appointments of masseurs in military hospitals are made without reference to the institute or association to which the individual applicant may happen to belong They are selected by an advisory committee consisting of masseurs, matrons and medical men Certain qualifications have been laid down which each candidate must possess before appointment and no candidate is rejected if possessed of the necessary qualifications

MONDAY, JULY 10TH

The Notification of Anthrax

Answering Mr W THORNE, Mr LONG (President of the Local Government Board) said The question of issuing an Order making all cases of anthrax compulsorily notifiable is under consideration

British Prisoners at Ruhleben

Answering Mr MALCOLM, who asked whether any reply had been received from the German Government on the question of the treatment of British civilian prisoners at Ruhleben, Lord ROBERT CECIL (Under Secretary for Foreign Affairs) said The note of the German Government, which was despatched within the time limited by our note has now reached us It denies that insufficient food is being given to the prisoners, and while rejecting our proposal as to exchange makes another proposal on the subject His Majesty's Government are considering what reply shall be sent to it, and will communicate the German note and our reply to the House as soon as possible In the meantime we are asking for a further report on the conditions at Ruhleben

Cases of Insanity amongst Men of the Navy

Mr MACNAMARA (Secretary to the Admiralty) informed Mr HOLLIER that men invalided from the Navy for insanity attributable to the service and in non-attributable cases those with length of service of 10 years and upwards to their credit were irrespective of the cause of insanity sent to Dartmouth Hospital The former about 10 in all at present were borne on full pay for a period of 18 months from first entry in a Naval hospital In non-attributable cases sent to Dartmouth pensions were not payable but the wives and children were granted small allowances out of Greenwich Hospital funds The total number of other Naval pensioners at present patients in public asylums was about 150 of whom about 15 were men discharged since the outbreak of war

in any other institutions than military war hospitals under the control of the War Office

Lord HENRY CAVENDISH BENTINCK asked whether any soldiers invalided through loss of mental balance had been discharged from the Army to asylums other than the three classes which he gave notice that he intended to discharge—viz cases of general paralysis of the insane chronic epilepsy, and nervous disturbance occurring in soldiers who had been in asylums before they joined the Army, and if so how many—Mr FORSTER answered A limited number of cases which after a period of from four to six months observation and treatment are considered to be incurable have been discharged to asylums The number is 193

TUESDAY JULY 11TH

Public Health Work

In the course of his speech in Committee of Supply on the Estimates of the Local Government Board, Mr LONG (the President of the Board) made a statement on various matters referring to public health Dealing with the work of local Poor law authorities, he said that they had provided a large number of beds for wounded soldiers in their institutions Accommodation had also been provided by the local authorities for infectious diseases amongst soldiers One half of the medical staff at the Local Government Board had been engaged on war work The work upon which they had been specially employed had been visitation of camps and billets and the inspection of food both at home and abroad He had it from heads of the War Department that it was believed it was in no small degree due to the co-operation of the Local Government Board and the admirable services of officers of that department that it had been possible to maintain so high a standard of food for the soldiers The Local Government Board had taken its part in the prevention of the spread of disease in the Army During the period of nearly two years when enormous numbers of men had been collected in certain areas there was too often no sanitary arrangement, but nevertheless the health of the country had been wonderfully maintained There had been a steady decrease in enteric fever Cerebro spinal fever, which at one time had caused a great deal of anxiety, was now practically causing the Board little or no anxiety Small pox which at one time caused some alarm in the country, had been satisfactorily dealt with There was no cause for anxiety now and this, he believed was due to the prompt action taken by medical officers of the Board No fewer than 3,000,000 tubes of lymph were supplied by the Board to the troops

Infant Welfare

Probably one of the most grave facts borne in upon honourable Members (the right honourable gentleman continued) was that the country was losing through the war many of the best and strongest of the male population Never was it more incumbent upon Parliament and the country than it was to-day to strain every nerve to see that the young members of the population were brought up so as to become healthy men and women I robust there was nothing more important than work connected with the welfare of infants and of women both before and after the birth of their children The Board had done its best to get local authorities to adopt schemes Most local authorities had willingly co-operated Schemes had been adopted for safeguarding the health of expectant mothers nursing mothers and of infant and young children Nearly all the large urban districts had adopted these precautions The Notification of Births Act 1915 had already had very excellent effects and he believed that as time went on admirable results would follow from this important change in the law Grants had been made to local authorities Nine hundred health visitors had been appointed and there were also a great many voluntary societies interested in the work Nursing associations were doing admirable work and there had been visitation inspection and advice by the inspectors of the Local Government Board There had been a decrease in infantile mortality It had gone down to 110 per 1,000 in 1915 and the first quarter of 1916 showed a much lower rate than the corresponding quarter of last year He thought there had been a tendency for Government departments to take up work which really belonged to a local department and the result was overlapping The Local Government Board was a department which ought to be charged with the health of the country There ought to be no interference with the department

Mr WHITFOOT asked whether the right hon. gentleman thought that the medical inspection of the

say that he had been able to adopt to a very large extent at all events the recommendations of the Commission. He desired to pay a tribute of gratitude on behalf of the Government and the House of Commons to the Commission for the splendid work which it had done. There were no diseases which had done more injury to the life of the people and more destroyed their soundness than had venereal diseases. Their consequences were terrible because these affected the succeeding generation. Nothing was more horrible than to see little children who had inherited venereal disease. He believed that if the recommendations of the Commission were followed consistently in the country a measure of relief would be given. The Commission had suggested that there should be facilities for diagnosis and treatment that these should be available for the whole population that they should be free of access, and it was recommended that if the work was done through the local authorities 75 per cent of the cost should be found by the State. The Chancellor of the Exchequer had agreed that that grant should be given. An announcement was made by him (Mr. Long) to that effect, and schemes were coming into existence. The counties and county boroughs were organising facilities in connexion with institutions. The Local Government Board was issuing an Order of which he had approved the other day, imposing this duty upon local authorities. The measures which the Board was calling upon them to take were—(1) that there should be laboratory facilities for free diagnosis, (2) that there should be clinics at the general hospitals for treatment and (3) that there should be a gratuitous supply of the great remedy salvarsan. He had seen in one of the London hospitals a ward set apart for the treatment of venereal disease and he earnestly hoped that all the great hospitals in the country would give their immediate aid in this work. He knew that some of those responsible for hospitals entertained a fear lest the importation into their institutions of the treatment of this disease would injure the reputations of the hospitals. It would do nothing of the kind. It was only possible to deal with this fell disease satisfactorily if the provision was universal. If patients had to go long distances in order to get hospital accommodation he was afraid that they would not go, and the remedies would not be available for them. He was quite confident that there was no reason to fear that by offering facilities for the treatment of this disease any hospital in the country would suffer in credit or in the good opinion of those who supported it.

Appeal for Public Co-operation

He invited the co-operation of local authorities, hospital authorities, medical men and the public generally. He hoped that there might also be co-operation on the part of ministers of religion throughout the country who could do a great deal to help in this beneficent work. Naturally there was a feature attached to this disease which did not belong to ordinary troubles. The patient did not like it to be known that he or she was suffering from it. Patients wanted to conceal the fact. Therefore if they were to be dealt with great care must be taken not only that there was proper provision for their treatment, but that everything that could be done was done to enable them to get it without unnecessary identification. One of the conditions which he had endeavoured to establish in consequence of this was that it should not be considered essential that a person coming to a hospital for treatment should belong to the district which the hospital served. He was requesting that questions should not be asked so as to identify the patients outside with the terrible misfortune that had overtaken them. It was desired to cure them and to eradicate this horrible disease. It could be done. If the Government received the assistance of people of all classes he believed that the time was no very far distant when this disease might be added to those the permanent ill-effects of which had been eradicated by satisfactory treatment.

Sanatoriums

Although there was a shortage of medical men there were to-day 291 sanatoriums and hospitals and 11,743 beds which had been provided for the treatment of tuberculosis in England. There had also been 359 dispensaries provided and there was to-day sufficient accommodation for our patients. All soldiers and sailors suffering from tuberculosis could be provided for in these institutions. A lot of the men were injured persons and arrangements in their case were made through the Insurance Committees. There were many soldiers and sailors who were injured and for them arrangements were made by the Local Government Board through the local authorities. There was a special arrangement for the treatment of officers. The Government was allowing a normal work in connexion with the hospitals to be done at which it was embarrassing, on the one hand, and it was impossible to do it in the ordinary course of life as a work and of protecting women

and children from the mortality which followed from preventable diseases. Some of those diseases, if they were not actually traceable to were undoubtedly aided and abetted by overcrowding, insanitary conditions in the homes, and by many of those social evils which had existed through so many generations and of which he was sorry to say the solution was not yet in sight. The Board had done its best to maintain the sanitary services. On the whole the record which he was able to present was not unsatisfactory.

Tribute to the Medical Profession

After the war there were many problems which would present themselves for immediate solution—the housing of the people, public works, and further health provision. The Government had set up a Reconstruction Committee, and all these problems were under careful survey and examination. The nation must realise that the health of the people was a matter of first consideration. In some respects there was great room for improvement. Throughout the last year or two there had been an immense amount of voluntary work on the part of people of all classes. He desired to pay a special tribute to medical men throughout the country. Insurance work had thrown upon them an immense burden of work. A very large number of them had joined the Royal Army Medical Corps. That diminished the number available for work at home. Cheerfully and bravely had these men done their work. Let anyone examine the diary of their day's work and see what they were accomplishing. There was no grumbling. The nation owed a special debt of gratitude to these men who were labouring in order that the population might be kept in good health. None at home were doing more than they were at present.

In the debate which followed general satisfaction was expressed with the statement made by the President of the Local Government Board.

Appointments.

Successful applicants for vacancies Secretaries of Public Institutions and others possessing information suitable for this column, are invited to forward to THE LANCET Office directed to the Sub-Editor not later than 9 o'clock on the Thursday morning of each week such information for gratuitous publication.

BARNOW G. A. M.R.C.S. L.R.C.P. Lond. has been appointed Assistant to the Manchester Royal Eye Hospital.
BRONLEY L. M.B. M.C. Cantab. F.R.C.S. Eng. Assistant Surgeon to Guy's Hospital.
CONSTABLE EVELYN A. M.B. B.S. Durb., Surgical Registrar to the London Temperance Hospital.
DORFORD A. C. L.S.A. Lond. Certifying Surgeon under the Factory and Workshop Acts for the Faringdon District of the county of Berks.
HACKETT J. A. W. M.B. Ch.B. Bdin. Certifying Surgeon under the Factory and Workshop Acts for the Gainsborough District of the county of Lincoln.
LLOYD J. T. M.R.C.S. L.R.C.P. Lond. Certifying Surgeon under the Factory and Workshop Acts for the Tregaron District of the county of Cardigan.
EAKESBOROUGH HILDA M.B. B.S. Lond. Assistant Resident Medical Officer at Queen Charlotte's Lying-in Hospital.
THORNTON ROBERT HENRY, M.B. Ch.B. Viet. Manch. Acting Deputy Medical Officer of Health for the Brixham (Devon) Urban Council.

Notes, Short Comments, and Answers to Correspondents.

THE UNIFORM SYSTEM OF HOSPITAL ACCOUNTS

A UNIFORM system of keeping accounts has long been adopted by the principal British hospitals and by, amongst others, the Governments of Victoria Queensland, and New Zealand, with several Crown Colonies. It is also in force at the principal hospitals in New South Wales, South Australia, Western Australia, Tasmania, and South Africa. The system has not yet been adopted in the Dominion of Canada, possibly on account of the difference of currency. By the use of the system expenditure at the various hospitals can be compared quite irrespective of their size for by a slight modification of some of the books used a cottage hospital of 50 beds or less can adopt the same bookkeeping method as a large hospital.

A new edition of Sir Henry Burdett's book¹ has appeared at an opportune time, as new hospitals are being established all over the land. It is of interest to note that the "Uniform System of Accounts" originated at the Queen's Hospital, Birmingham, in 1869 and was devised by the author with the cooperation of the late Mr William Lundy, a well known Birmingham accountant. Six years later the system was introduced into the Seamen's Hospital at Greenwich, and was soon after adopted by a few of the larger hospitals. The Metropolitan Hospital Sunday Fund then prescribed its use by the hospitals applying for grants and a revised form was recommended by the Saturday Fund and King Edward VII's Hospital Fund. These three great hospital Funds now propose that the accounts of all institutions applying for grants from either of the three Funds should be audited and certified as correct by a chartered or incorporated accountant, who should be asked to satisfy himself that all the accounts are prepared and stated in accordance with the revised "Uniform System." Quite recently the Army Council has issued instructions that all hospitals run by the British Red Cross Society or by the Order of St John should have their accounts kept on the "Uniform System." Sir Henry Burdett's book has therefore become a semi-official publication.

WEIHAIWEI HEALTH REPORT

REPORTING on the affairs of Weihaiwei, the naval and military station in the province of Shantung leased to Great Britain by China in 1898, Sir J. H. Stewart Lockhart K.C.M.G., the British Commissioner, states that during 1915 the health of the territory was very satisfactory. There were no cases of infectious disease reported except one case of paratyphoid from which a visitor suffered, and one case of measles. One case of leprosy occurred which was received by Dr Fowler into his leper house at Hsiao Han. The administration expresses its indebtedness to him for having received this patient and to Dr Wassel of the American Church Mission, who happened to be paying a visit to Weihaiwei, for having kindly escorted the patient to the Leper Home. In the hospital at Port Edward 70.3 out patients and 265 in patients were treated making a total of 8074, as compared with 6770 in 1914 and 2307 in 1907. The number of operations performed was 356 as against 335 in 1914 and 15 in 1907. In the hospital at Wenchuan'ang 3825 new patients were seen as compared with 3923 in 1914. 45 cases were treated as in patients and 24 cases were attended at their own homes. In November the new hospital on the island was opened and is a great improvement on the former building. During the year 4530 vaccinations were performed. The number of persons licensed to smoke opium on medical grounds was 38 (as compared with 27 in 1914) their average age being 62.5 years. The number of convictions under the Ordinance prohibiting the smoking and importation of opium was 59. The highest temperatures recorded at Port Edward during 1915 was 99° in July and the lowest 71 in January, rain or snow fell on 65 days, the total fall for the year being 17.66 inches. At Wenchuan'ang situated about 13 miles from Port Edward the highest temperature was 90 in July and the lowest 16 in January and February, rain or snow fell on 64 days, the total fall for the year being 20.22 inches.

¹ The Uniform System of Accounts for Hospitals and Public Institutions. Orphanage, Mission, and Social Service. By Sir Henry Burdett. 4th Edition. London: H. K. Lewis, 1915. Pp. 122. 1s. 6d. net.

PUERPERAL FEVER IN THE SUDAN

THE report upon the research work of the Wellcome Tropical Research Laboratories at Khartoum during 1915, which is not published in full on account of war economy, contains a summary (*Tropical Diseases Bulletin*, vol. vii, No. 6) of an investigation by the director, Dr. A. J. Chalmers and Dr. Alex. Marshall into the bacteriology of puerperal fever. They found this to be in the Anglo Egyptian Sudan mostly a local uterine infection and not commonly a septicæmia. Two causal organisms were *S. salivarius* and *S. bovis* (= *S. borinus*, Broadhurst, 1915). The writers also found cases in which the causal organism was *S. versatilis*. Broadhurst, 1915 a member of the *faecalis* group and another due to *S. faecalis*, Andrewes and Horder, 1906. The sources of infection appeared to be principally from human, equine, and bovine fæces the two latter being largely used in Khartoum and Omdurman as an application called "Zibla" which is applied to roofs and walls. Cow dung is also used as a poultice by the natives.

Messrs C and J—Sterile catgut is manufactured in Edinburgh by Messrs G F Marson and Co., 7, Meuse lane, South St Andrew street.

Messrs B—The apparatus for chloroform anaesthesia in military practice described by Professor A. D. Waller in THE LANCET of May 13th is made by Messrs Coxeter and Son, of 171, Pancras road, N. W.

The following magazines, journals &c., have been received—*Science Progress*, *Dublin Journal of Medical Science*, *Tropical Diseases Bulletin*, *Calcutta Medical Journal*, *St. Bartholomew's Hospital Journal*, *Edinburgh Medical Journal*, *Birmingham Medical Review*, *Medical Review*, *Review of Neurology and Psychiatry*, *Archives of Radiology and Electrotherapy*, *American Journal of Public Health*, *Journal of State Medicine*, *Cleveland Medical Journal*, *British Journal of Tuberculosis*.

Medical Diary for the ensuing Week.

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street W

MEETINGS OF SECTIONS

Thursday July 20th.

DERMATOLOGY (Hon. Secretaries—A. M. H. Gray, J. E. R. McDonagh): at 5 P.M.

Cases: Dr. G. Pernet: (1) An Extensive Case of Lupus Vulgaris of Leg following a Tuberculous Abscess. (2) Dermatitis Herpetiformis in a Boy. (3) Multiple Lupus Vulgaris with Unusual Features in a Girl.

Friday July 21st.

SURGERY (Hon. Secretaries—Raymond Johnson, V. Warren Low): Special Meeting at 5 P.M.

Paper: Major Tait McKeown, R.A.M.C.: The Treatment of Convalescent Soldiers by Physical Means (illustrated by lantern slides of cases under treatment).

Members of other Sections are cordially invited and the paper will have special interest for Members of the Sections of Bacteriology, Electro-therapeutics and Neurology.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE West London Hospital, Hammermith road W.

Monday—2 P.M. Medical and Surgical Clinics X Rays Mr Gray: Operations Mr B. Harman; Diseases of the Eye. Dr. Simson; Diseases of Women.

Tuesday—2 P.M. Medical and Surgical Clinics X Rays Mr Baldwin; Operations Dr. Banks Davis; Diseases of the Throat, Nose and Ear. Dr. Pernet; Diseases of the Skin.

Wednesday—10 A.M. Dr. Saunders; Diseases of Children. Dr. Banks Davis; Operations of the Throat, Nose and Ear. 2 P.M. Medical and Surgical Clinics X Rays Mr Pardo; Operations Dr. Simson; Diseases of Women.

Thursday—2 P.M. Medical and Surgical Clinics X Rays Mr Gray: Operations Mr B. Harman; Diseases of the Eye.

Friday—10 A.M. Dr. Simson; Gynecological Operations. 2 P.M. Medical and Surgical Clinics X Rays Mr Baldwin; Operations Dr. Banks Davis; Diseases of the Throat, Nose and Ear. Dr. Pernet; Diseases of the Skin.

Saturday—10 A.M. Dr. Saunders; Diseases of Children. Dr. Banks Davis; Operations of the Throat, Nose and Ear. Mr B. Harman; Eye Operations. 2 P.M. Medical and Surgical Clinics X Rays Mr Pardo; Operations.

NORTH EAST LONDON POST GRADUATE COLLEGE Prince of Wales General Hospital Tottenham.

Monday—Clinics—10.30 A.M. Surgical Out-patients (Mr. E. Gillespie); 2.30 P.M. Medical Out-patients (Dr. T. R. Whippleham); Gynecological Out-patients (Dr. Banister); 3 P.M. Medical In-patients (Dr. R. M. Leslie).

Tuesday—2.30 P.M. Surgical Operations (Mr. Carson). Clinics—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. C. H. Hayton); Radiography (Dr. Metcalfe); 3.30 P.M. Medical In-patients (Dr. A. J. Whiting).

Wednesday—Clinics—2.30 P.M., Throat Operations (Mr. C. H. Hayton); Children Out-patients (Dr. T. R. Whippleham); Eye Out-patients (Mr. R. P. Brooks); Skin Out-patients (Dr. R. W. Barber); 5.30 P.M. Eye Operations (Mr. R. P. Brooks). Thursday—2.30 P.M. Gynecological Operations (Dr. A. E. Gillespie); Clinics—Medical Out-patients (Dr. A. J. Whiting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe); 3 P.M. Medical In-patients (Dr. R. M. Leslie). Friday—2.30 P.M. Surgical Operations (Mr. Howell Evans); Clinics—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. E. Gillespie); Eye Out-patients (Mr. R. P. Brooks).

THE THROAT HOSPITAL, Golden square W.

Monday—5.15 P.M. Special Demonstration of Selected Cases.

Thursday—5.15 P.M. Clinical Lecture.

EDITORIAL NOTICES

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES

THE INDEX AND TITLE-PAGE TO THE LANCET

January to June, 1916

In view of the Government restrictions upon the supply of paper, and the shortage of paper quite apart from these restrictions, the Index and the Title page to the volume of THE LANCET which was completed with the issue of June 24th have been printed separately, and copies have been supplied gratis to those subscribers who have up to July 13th, intimated to us their wish to receive them. Other subscribers will be similarly supplied, so long as the stock remains unexhausted on application to the Manager THE LANCET Office, 423 Strand London, W.C. Such application should please be sent in at once.

Volumes and Cases

VOLUMES for the first half of the year 1916 will be ready shortly. Bound in cloth, gilt lettered, price 16s, carriage extra.

Cases for binding the half year's numbers are now ready. Cloth, gilt lettered, price 2s. by post 2s. 4d.)

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423 Strand London W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers by sending their subscriptions direct to THE LANCET Offices will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

TO COLONIAL AND FOREIGN SUBSCRIBERS

Subscribers abroad are particularly requested to note the rates of subscription given on page 4.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied.

An Inquiry

INTO

THE CARDIAC DISABILITIES OF
SOLDIERS ON ACTIVE SERVICEBY JOHN PARKINSON, MD LOND
MRCP LOND,JUN ASSISTANT TO THE CARDIAC DEPARTMENT OF THE LONDON
HOSPITAL, TEMPORARY CAPTAIN, L.A.S. C. ATTACHED
RAMPSFORD MILITARY HOSPITAL FOR HEART CASES

THIS paper records the result of an inquiry into the various conditions which lead men on active service to port sick with symptoms suggesting heart disease. It is based on 93 cases seen as they passed through a casualty clearing station with the British Expeditionary Force in France from March 1915 to January 1916, every patient sent to my wards from a field ambulance with the diagnosis heart disease or disorder was investigated. There was no selection of patients so referred was rejected as unsuitable, as the series is consecutive. During a large part of this period the clearing station was in reserve hence the number seen gives no indication of the frequency of these disabilities or of their proportion to the total sick. Disadvantages in this inquiry were the short period of observation usually two or three days and the absence of special means of investigation. It was however an advantage to see the men so shortly after they had reported sick.

METHOD OF INVESTIGATION

A detailed history of the patient was first obtained on occasions recent and remote were followed by an account of his capacity for exertion at school and at work. After enlistment the effects of training and of campaigning were noted then the immediate reasons for his reporting sick. It was found that about an hour was necessary to obtain a satisfactory history large part in the man's own words and without the use of leading questions.

On examination attention was directed to the patient's general condition and temperament. The position of the apex beat with the patient recumbent was used as a guide to the size of the heart. A standard amount of exertion served as a test for the functional efficiency of the heart.

A. NON-CARDIAC CONDITIONS (22 Cases)

When the difficulties of field ambulance work are considered it is no surprising to find that in a number of patients the symptoms were due to other than heart disease. There were 22 among the 93 cases in whom other states were demonstrable. Of these 2 had acute and chronic nephritis 1 acute and 1 chronic bronchitis. One patient had an enlarged thyroid gland with tachycardia, no other had a pulse without symptoms of thyrotoxicosis. Three cases were seen as D.A.H. (disordered action of the heart) because of syncope alone and 3 others because they showed an unusual degree of normal sinus arrhythmia. The 7 remaining cases were considered respectively symptoms of pulmonary tuberculosis, an aneurysm, chronic lumbago, an immersion debility, epistaxis and lymphadenoma.

B. VALVULAR DISEASE (2 Cases)

Among the 93 cases valvular disease was present in 23. Of these 8 had mitral incompetence and mitral stenosis 8 had incompetence alone 1 had stenosis alone and 2 acquired aortic stenosis (hemorrhagic history, thrill and pulmonary congestion) and aortic and mitral incompetence and aortic stenosis. The stenosis was doubtful. For convenience a case of thoracic aneurysm and one of dextrocardia are included in this series of 23. In 15 cases there was a full set of electrocardiograms. In 18 the chief symptoms were breathlessness in 6 it was pain, all cases with a full set of electrocardiograms. Palpitation was an important symptom in half the cases. Five patients of whom 6 had aortic stenosis complained of giddiness. A faint feeling or syncope had occurred in one case of aortic stenosis and in one of pulmonary stenosis. Two patients complained of great exhaustion on the march and two of aches of the legs on exertion. The symptoms were

provoked by doubling and marching and in 25 cases they had been present before enlistment. One man of 40 with a to-and-fro ('owlows') murmur at the aortic area yet without displacement of the apex beat had served 16 months including six at trench work in France. He had no symptom whatever and the aortic incompetence was discovered at a chance examination.

C. SO-CALLED SOLDIER'S HEART (49 Cases)

(1) Etiology; (2) Symptoms; (3) Physical signs; (4) Exertion test; (5) After-history; (6) Nature of the condition; and (7) Conclusions.

After dismissing briefly the cases with non-cardiac conditions and those with valvular disease, there remain 40 patients to be considered more closely. They were men who complained of cardiac symptoms, especially breathlessness and precordial pain but in whom no physical sign of heart disease could be found. In the Army Medical Service they would be classified under D.A.H., and in medical literature they have been referred to as "soldier's heart." The terms irritable heart and "heart strain" have been employed but their use is open to criticism. These 40 cases are summarised at the end of this paper, the full notes on them are the foundation for the following statements on the etiology, symptoms and signs of this group of patients and for the subsequent discussion on the nature of the condition.

ETIOLOGY

Age—The average age of these patients was 30 years. Of men between the years 17 and 20 there were 6, between 21 and 30 17, between 31 and 40 9, and between 41 and 50 8. One patient aged 51 was the only man above 45 years of age.

1. Incidence—(a) Before enlistment. Four patients gave a history of acute rheumatism and 3 of them had symptoms before enlistment (Cases 11, 18 and 19). Two men (Cases 13 and 16) had contracted enteric fever during the South African War. 2 gave a history of pneumonia, and 2 of pyrexia of unknown origin (Cases 3 and 24). The following infections had occurred each in one case: syphilis, diphtheria, repeated colds (Cases 21, 4 and 6). Thus in 12 out of 40 cases there was a history of an infection which may have been the cause, and 6 of these had symptoms before the war. In addition 7 patients said they had scarlet fever in childhood though none diphtheria. (b) After enlistment. In 5 patients previously healthy, cardiac symptoms followed immediately upon an illness during military service. In 2 of them (Cases 9 and 10) influenza preceded an attack of angina pectoris, in the remaining 3 symptoms appeared after trench feet and lumbago (Case 25), lumbago (Case 33) and pains in back and joints (Case 23).

2. Tobacco—Two men admitted that they were heavy smokers. Sixteen smoked cigarettes and claimed to be moderate (5-10 a day). Ten smoked a pipe (1-3 oz. weekly), rarely cigarettes. Four smoked little, not more than one or two cigarettes a day and 1 was a non-smoker (Case 21). In 7 there is no note as to smoking. It is noteworthy that about half the cases either smoked a pipe or were very light smokers.

3. Alcohol—Ten patients were total abstainers, three had been "at the heart" beer drinkers before they left England, as usual had been less in France. The remainder may be considered moderate drinkers.

4. Military service—Among 40 cases only 4 gave a history anterior to the onset of symptoms to a particular exertion. Case 3 first noticed precordial pain after marching several miles with a full pack on a hot day, recovered on subsequent moderate exertion. Eight months before he had been confined to bed for five weeks with influenza. Cases 9 and 10 suffered from an attack of angina pectoris during exertion but each had recovered to date after influenza. Case 21 experienced no symptoms until subjected to an unusually severe trench work and then slight breathlessness and pain preceded by three weeks the sudden onset of severe pain while carrying a heavy weight.

5. Physical signs—In two only among the 40 patients was there evidence of enlargement of the thyroid gland and they are included above in the non-cardiac series. No aortic pulsation considered as "soldier's heart" showed enlargement of the chest or any other signs or symptoms which, combined, would justify a diagnosis of hypertrophy.

Symptoms

An unexpected result of inquiries into the medical history of patients before enlistment was the frequency with which similar symptoms had been present for years before the war. This was true of no less than 29 of the 40 cases. In support of their assertion is the fact that 24 of these had symptoms as soon as they began to train, the remaining 5 had little or no training. Seven had been compelled to obtain lighter civil employment because of their disability. If we except 9 men whose symptoms had only been slight before enlistment ("always short-winded") there remain 20 out of 40 exactly half the cases, who had had on exertion definite shortness of breath, palpitation, or pain before they joined the Army.

That the symptoms arose from the heart can scarcely be questioned. The dependence of the breathlessness and pain upon exertion and the frequency of precordial pain are characteristic. The symptoms are identical with those shown in valvular disease.

In all cases shortness of breath was induced by exertion and was absent during rest except in Cases 11 and 21. Under training doubling was almost invariably mentioned as the source of greatest difficulty, indeed, many were excused doubling on this account. Marching produced shortness of breath or precordial pain. Several complained of symptoms when marching to and from the trenches, but said they felt well enough while in them. Among mounted men, riding at a moderate pace was tolerated, but trotting invariably induced their symptoms. In 4 cases the excitement of shell fire provoked palpitation or giddiness (Case 25), precordial pain (Case 35) and palpitation (Cases 33 and 36).

(a) *Shortness of breath*—This was present on exertion in every case except one (Case 3).

(b) *Pain*—Pain had occurred in 24 cases—i.e., more than half, in 6 it was severe, in 14 moderate, and in 4 it was slight. With one exception (Case 3), all patients with pain had also some breathlessness on exertion. Needless to say, the patient's own diagnosis of pain over the heart was not accepted without criticism. He was asked to point to the site and this is indicated in the summarised histories. The pain was usually of an aching character, with more severe exertion it became sharp. It was limited to the region of the apex beat in 8 cases to the fourth left space (anteriorly) in 3, and to the fifth space in 2. In 4 patients the pain occurred in a larger area including the third, fourth and fifth spaces. Three men described severe pain with extension down the left arm which might permit its description as *angina pectoris* (Cases 9, 10 and 11). Of a different character was the pain in Cases 28, 29 and 36, who felt a gripping sensation across the lower half of the front of the chest as the result of effort. Cases 25 and 28 complained of a "weak feeling" in the left breast and left arm respectively, and Case 7 of cramp in the left arm. In two patients the pain was felt at the left costal margin and may not have been cardiac.

(c) *Palpitation*—This was one of the complaints in 26 of the 40 cases and a prominent one in 9 cases (Cases 32-40). Nine felt it during exertion, 9 others particularly on excitement but also on exertion. In 2 of the 5 patients whose description suggested irregularity of the heart premature contractions were noted clinically.

(d) *Giddiness*—This was present in half the patients and a prominent symptom in Cases 1 and 14. It usually accompanied the other symptoms on exertion.

(e) *Exhaustion*—This is a complaint difficult to assess in a medical history. Sixteen patients said that they were easily exhausted—e.g., on the march, weakness of the legs was specially mentioned by 3 as one of the symptoms which made them fall out on the march.

(f) *Other symptoms*—Sweating was mentioned by 6 men as one of their complaints. "Faint feelings" were a source of trouble to several men and actual syncope had occurred since enlistment in 3 (Cases 15, 23, and 35). Repeated headaches had troubled 3 patients.

Nervousness—It will be remarked in glancing through the summaries that 9 cases (Cases 32-40) differ to some extent from the rest. Palpitation was a prominent symptom with them and had been present in 7 cases for years, it is noteworthy that they also had breathlessness on exertion. Of these 9 patients 5 (Cases 32, 35, 35 and 36) were of a nervous temperament and had readily been easily excited, both in appearance and manner the

remaining 4 were normal. The first two of the nervous patients said, "My nerves are gone" and "I cannot sit it." The attacks in Cases 32, 33 and 37 were similar. They were induced by excitement as well as by exertion. Palpitation was accompanied by "falloes in the throat," tingling of fingers or coldness of feet, and sweating. In attack lasted from half an hour to an hour during which time the patient felt quite exhausted, "dead beat."

Physical Signs

As cases with valvular disease of the heart and diseases other than cardiac have been separately considered above it is to be expected that abnormal physical signs will be few. The physique and general appearance of the patients did not differ greatly from that of other medical cases admitted to the clearing station. A few of the temperaments are cited above when describing symptoms.

The rate of the pulse—The average pulse rate among the 40 patients, while lying down, was 75 per minute. It was below 70 in 12, between 71 and 80 in 13, and between 81 and 90 in 11 cases. In 3 patients only was the rate higher than 90. In Case 25 it was found to be 92-104 on five successive days, in Case 22 it was 90-96 on three successive days, in Case 13 94-110 on three days of observation. It will be seen that while it is higher than that of normal men the average rate among patients with "soldier's heart" is not high, so that tachycardia is not a feature of the group as a whole. For the effects of posture and exertion on the pulse rate see the section on exertion tests.

The site of the heart—In the absence of opportunities for orthodiagraphy and recognising the unreliability of percussion in slight changes in size it was decided to use the position of the apex beat as the guide, with the patient recumbent. Among my 40 patients this was felt in the fifth (occasionally fourth) space, interval to the nipple line in 23 cases, in the nipple line in 6 cases, and just external to that line in 2 cases only (Cases 12 and 19). In no case was the impulse felt in the sixth intercostal space. In 9 cases the apex beat was not palpable, but to percussion the heart was not enlarged. Hence evidence in favour of enlargement of the heart was only present in two cases (Cases 12 and 19) unless palpation of the apex beat in the nipple line is regarded. In the 6 cases where this was its position not even a faint murmur was heard.

Auscultatory signs—There was no alteration in the heart sounds and no murmur in 26 cases out of 40. In Cases 2 and 11 the heart sounds were distant and in Cases 1, 16, and 19 (y r) they were modified. A short soft systolic murmur was heard at the apex in 9 cases only, and in them the pulmonary second sound was not accentuated. In 5 of these where the test is noted the murmur was absent on standing.

In Cases 2, 26 and 37 the radial arteries were thickened more than usual at their ages—43, 51, and 33 years respectively, but their urine contained no albumin, and there seemed little in favour of considering their symptoms to be due to arterio-sclerosis. The urine was examined in 21 cases not in the earlier patients seen, and was free from albumen. Premature contractions were noticed in 3 patients and in Case 32 they occurred after every normal beat (paroxysmal bigeminy).

Exertion Test

In all but three cases the following exertion test was applied. After the patient had been lying on his back for half an hour the pulse rate was taken by palpation counting one-half minute. He was then told to stand and the pulse rate was immediately counted during the next half minute. Then he was accompanied while climbing 23 steps at a moderate pace and his pulse was again taken in the same way. The symptoms provoked were recorded and controlled by observation. The object was twofold: first to determine the functional efficiency of the heart in noting the symptoms produced in different patients for the same amount of exertion, and secondly to determine the increase in pulse rate bore any relation to the severity of the symptoms produced.

1. *The symptoms induced by a standard amount of exertion as a test of myocardial efficiency*—In the absence of physical signs of heart disease symptoms assume an especial importance and a clinical test which reproduces them becomes most necessary. Five patients (Cases 10, 11, 22, 23 and 36) showed rather severe shortness of breath when they were

hurry September, 1915 to France Palpitation shortness of breath, exhaustion and dull pain in fourth to sixth left spaces about nipple line all on marching After one month admitted Examination No abnormal physical signs Eight months later Full duty in France, but no exertion

CASE 7—Private — (4228), aged 28 History At school and at light work as packer easily out of breath, "wind" never good Palpitation dizziness and occasional precordial pain on exertion Mar 1915 enlisted Sharp pain in left breast and shortness of breath at drill Slight dizziness September to France Sharp pain from third to fifth space in nipple line and shortness of breath whenever marching with pack Palpitation also at night After one month admitted to C.C.S. (October) Examination No abnormal signs Eight months later Hospital, improved, still pain

CASE 8—Private — (1129), aged 30 History Since at school and while a labourer, palpitation, precordial pain and breathlessness on exertion September, 1914, enlisted November, to France, palpitation and exhaustion during trench work. Since August 1915 breath very short on march with sweating and palpitation October, admitted Examination Apex beat fifth space, internal to nipple line Short soft systolic murmur at apex, disappearing on standing Seven months later Garrison duty, no better

CASE 9—Private — (469) aged 28 History Wheelwright, quite well December 1913, joined Reserve August 1914 to France Quite well until two weeks before admission, when he was in bed four days with "influenza" (headache, pains in chest loss of voice) On return to sentry work, precordial pain on walking, While in bed attacks of severe pain beginning in fourth left space and extending down inner side of left arm The pain lasted about five minutes and recurred every hour, it left the arm weak and tingling No shortness of breath during the attacks A week later, February, 1915, admitted Slight precordial pain on admission Examination Apex beat, fifth space in nipple line Heart sounds normal, no murmurs. Fifteen months later Still some pain January, 1916, discharged permanently unfit

CASE 10—Private — (997), aged 21 History Farm labourer, quite well August 1914 mobilised from Reserve and sent to France One month before admission, "influenza" in bed three days with pyrexia, weakness, and cough On returning to duty experienced attacks of sharp pain from apex beat to anterior fold of axilla and down left arm to elbow These attacks were induced by exertion as lifting and lasted several minutes stopping suddenly He also found himself short of breath on moderate exertion March 1915 admitted Examination Apex beat, fifth space, internal to nipple line Heart sounds normal Fourteen months later Light duty, almost well

CASE 11—Sergeant — (54818) aged 36 History Aged 17 to 29 in Army In 1908 acute rheumatism, discharged from Army Since aged 32 farinacean, shortness of breath and palpitation on severe exertion Syncope three times August 1914, re-enlisted Attack of orthopnea and edema after exposure at a review Improved and went to France in Mar 1915 Precordial pain and breathlessness on severe exertion Five days before admission, while carrying telephone wire under fire felt sudden pain at apex beat shooting down left arm "I thought I was shot" Fell down very short of breath Left arm remained sore and weak. Two days later similar attack but with unconsciousness, left arm useless Two days later August, admitted Examination Slight breathlessness, no pain Apex beat no felt area of cardiac dullness not enlarged Heart sounds distant no murmur

CASE 12—Private — (23561) aged 20 History Age 12 to 16 new boy much running and exposure Carpenter Pain at apex beat and breathlessness on exertion during three years before enlistment September, 1914 enlisted Precordial pain and shortness of breath on marching during training and since arrival in France November, 1915 admitted to C.C.S. Examination Apex beat fifth space just external to nipple line Heart sounds normal short faint systolic murmur at apex absent on standing Pulse 60 Seven months later Garrison duty no better

CASE 13—Private — (5183) aged 35 History Age 20 enteric fever in South African War Age 25 to 34 boiler maker heavy work quite well August 1914 mobilised from Reserve Fell out on march during training and in France with breathlessness palpitation and exhaustion July 1915 after six miles marching while very short of breath felt his heart stop became giddy and fell down faintly After admission Examination Apex beat fifth space internal to nipple line Heart sounds slightly faint no murmur Five months later No better or discharged permanently unfit

CASE 14—Driver — (3594) aged 33 History Labourer but had to stop light work because of shortness of breath on

exertion August, 1914, enlisted During training and later in France riding produced breathlessness and palpitation The breath became worse "couldn't possibly run," and he became giddy even on mounting a horse November, 1915, admitted Examination No abnormal signs Six months later Base duty, no better

CASE 15—Private — (5132), aged 19 History Machinist. Frequent faint feelings Shortness of breath and palpitation on over-exertion Could not cycle as far as his friends September 1914, enlisted Fell out at drill and on the march with breathlessness August 1915 to France, same symptoms and also syncope November, admitted Examination Apex beat not felt Short faint systolic murmur at apex, absent on standing Six months later Still in hospital, no better

CASE 16—Gunner — (62006), aged 36 History Labourer Age 30, obtained lighter work on account of shortness of breath palpitation and giddiness on exertion Heavy beer drinker September, 1914, enlisted Breathless on doubling, discharged from Army January, 1915, re-enlisted June, to France. Unable to march because of breathlessness, precordial pain at apex beat, palpitation and exhaustion Examination Apex beat not felt Short soft systolic murmur at apex. Second sound duplicated at all areas Pulse 84, small volume, artery not thickened Six months later Base duty, no better

CASE 17—Private — (12074), aged 30 History Metal polisher Good boxer in youth Since age 24 palpitation on excitement and in bed Games relinquished for this reason and for shortness of breath August, 1914 enlisted Work in stores June, 1915, to France Fell out on march or on handling sacks, because of breathlessness, palpitation, and faint feelings November, admitted Examination Apex beat, fifth space internal to nipple line Short soft systolic murmur at apex. After six months Home service, deserted April, 1916

CASE 18—Corporal — (1339), aged 42 History Age 19 to 31 in 17th Lancers "Was your wind fairly good?" "No, my breath has never been what it should be" Age 27, enteric fever during South African War Age 39 and 41 acute rheumatism Age 31 to 41 in Reserve, light work, breath short on walking home, a mile January, 1915, re-enlisted, to France as mounted police Breath short when trotting September, after trotting 500 yards sudden severe pain in fourth left space, internal to nipple line, localised, lasted ten minutes, breath short "I felt that my last day had come" Since this attack pain and breathlessness whenever he tries to trot December admitted Examination No abnormal physical signs Five months later Light duty, no better

CASE 19—Private — (18581) aged 30 History Shopman Never played games, "I could never run without being puffed" Age 24, acute rheumatism Breath became worse, occasional pain in sixth left space about nipple line Mar, 1915 enlisted Excused drill and marching because of breathlessness September to France On marches to and from trenches shortness of breath precordial pain (sixth space in nipple line) palpitation and dizziness December, admitted Examination Apex beat fifth space, half inch external to nipple line First sound resembles second at apex No murmurs Six months later Full duty in France

CASE 20—Private — (7559), aged 17 History Age 12, acute rheumatism (?) Painter Long winded good cyclist June 1915 enlisted "Training did me good" Long route marches well borne November (seven weeks before admission) to France Exhausting trench work, no colds or other illnesses Three weeks ago began to notice breathlessness slight throbbing pain in left breast, and exhaustion all on exertion A week ago while carrying a heavy waterpipe felt a pain and strained feeling in the left breast second to fifth spaces, with giddiness and shortness of breath January 1916, admitted Examination No abnormal physical signs The aching in the second third and fourth spaces persisted during a week in bed Five months later Still in hospital, much better

CASE 21—Sergeant — (9050), aged 42 History Age 18 to 35 in Army good runner Age 28 syphilis Age 35 left Army and became miner Began to notice shortness of breath on heavy exertion March, 1915 re-enlisted May, to France, short of breath on a long march From November more breathlessness and some pain below left breast fifth to seventh spaces on marching January, 1916, admitted Examination Slight shortness of breath in bed Apex beat not felt Heart sounds normal no murmurs Four months later Light duty symptoms worse

CASE 22—Driver — (3594) aged 19 History Never long winded relinquished heavy work as fitter on account of shortness of breath and became messenger February, 1915 enlisted fell out on doubling with breathlessness October to France Shortness of breath on riding, to

hospital December again in hospital for same complaint January, 1916, admitted Examination No abnormal signs Five months later Base duty, no better

CASE 23—Private — (10918), aged 43 History Brick layer Aged 40, pneumonia One year breathless and giddy on hurrying June 1915, enlisted Unable to double or march far because of breathlessness and also giddiness Syncope three times January 1916, to France, reported sick with same symptoms and admitted to C C S Examination No abnormal physical signs Four months later Still in hospital improving

CASE 24—Private — (12016) aged 26 History Age 20 (1910), enlisted Good runner In 1913, five weeks in hospital in Egypt with pyrexia of unknown origin Two months later sent to England as D A H Gave up running because of breathlessness August 1914 mobilised and sent to France Exhaustion and pain in left breast at retreat from Mons Since December similar pain and also breathlessness on marching or on lifting Examination Apex beat, fifth space, internal to nipple line Short soft systolic murmur at apex, localised Pulmonary second sound not accentuated Four months later Full duty, but no better

CASE 25—Private — (11858), aged 22 History Porter, light work, well Good swimmer August, 1914, enlisted Training well borne November, to France, no symptoms February, 1915, to England with trench feet and lumbago November again to France Found himself breathless after marching a hundred yards Palpitation and giddiness under shell fire January, 1916, admitted Examination Nervous temperament No abnormal physical signs Pulse-rate remained about 100, lying during the five days under observation Four months later Seen personally in hospital, no better

CASE 26—Private — (7605), aged 51 History Mill worker Several years palpitation and breathlessness on heavy exertion September, 1914, enlisted Excused doubling and marching because of shortness of breath, palpitation, and weakness of legs November 1914, to France Since October, 1915, symptoms worse and accompanied by a weak feeling in the left breast January, 1916, admitted Examination Apex beat, fifth space, in the nipple line Heart sounds normal, no murmurs Arteries, moderately thickened, perhaps more than usual at his age Four months later Light duty, no better

CASE 27—Private — (18722), aged 41 History Labourer Three years breathless and giddy on heavy exertion March 1915, enlisted Excused all drill and marching because of breathlessness October, to France Fell out panting, on march, and admitted to C C S January 1916 Examination Apex beat, fifth space, in the nipple line Heart sounds normal, no murmurs Four months later Light duty, fairly well

CASE 28—Private — (55695) aged 30 History Brick layer quite well February 1915, enlisted Good marcher In France, July, off duty one week with pain in back and limbs On return to duty, palpitation and a weak feeling going into my left arm sweating and giddiness produced by exertion or excitement On running became "blown" and had pains across the front of the chest Examination No abnormal signs Nine months later After six months hospital, better, in India

CASE 29—Sapper — (132522) aged 44 History Labourer Three years short winded and troubled with palpitation October 1915, enlisted November to France Fell out on marches with palpitation exhaustion and shortness of breath Light duty January, 1916 admitted Examination No abnormal physical signs Four months later No better, discharged permanently unfit

CASE 30—Corporal — (11195) aged 19 History Mechanic Two years occasional sharp pain near left nipple with some difficulty in breathing August 1914 enlisted Doubling produced precordial pain and breathlessness but could march steadily April, 1915 to France A week before admission, while walking sudden giddiness shooting pain in left breast, and a stifling feeling Palpitation Bristled feeling from left nipple to armpit Several similar attacks since always with dyspnoea September admitted Examination Apex beat not felt No abnormal physical signs Eight months later Home service improved

CASE 31—Private — (12259) aged 32 History Age 15 pneumonia Till age of 27 waiter age 27 to 31 miner occasional pain across front of chest after long shifts No shortness of breath August 1914 enlisted On doubling he always felt a gripping sensation across the front of the chest so that he could scarcely breathe Similar symptoms on marching with full pack in training and since in France August 1915 admitted Examination Poor physique No other abnormal physical signs Nine months later Full duty but no better

CASE 32—Driver — (69599), aged 37 History Gait Several years attacks of giddiness sweating, and vertigo syncope several times Readily short of breath on exertion and subject to palpitation February, 1915, enlisted riding or drilling, breathlessness, dull pain in left palpitation, and exhaustion Easily excited March cold and numb August admitted Examination 7 and nervous No abnormal physical signs Nine months later Base duty, some improvement

CASE 33—Driver — (24779), aged 45 History Mechanic Amateur boxer till age of 25 Since 1913 occasional palpitation back, otherwise well September, 1914, enlisted October to France February, 1915, pains in back and attacks of palpitation with breathlessness and exhaustion, induced riding or by excitement Occasional aching pain at base of heart on trotting August, admitted Examination Apex beat not felt No murmurs A premature contraction heard after each normal beat Nine months later No better, discharged permanently unfit

CASE 34—Private — (1813), aged 19 History Carman Sharp pain limited to anterior part of fifth left intercostal space, on severe exertion Occasional attacks of dizziness and palpitation on exertion August, 1914, enlisted Since symptoms during training, marked Home service January 1915, to France Attacks of dizziness palpitation, and sweating Precordial pain (fifth left space only) and breathlessness on exertion August, admitted Examination Apex beat, fifth space, internal to nipple line No murmurs A premature contraction was heard after every few beats Nine months later Duty in India no complaints in letters home

CASE 35—Corporal — (279), aged 28 History Japanese Syncope at school and every few months since Nerve Fingers often "go dead" August 1914, enlisted Faint feelings at drill June, 1915, to France Exhaustion on march also some breathlessness Several weeks before admission, syncope and faint feelings Pain from left nipple to costal margin when under fire October, admitted Examination Depressed appearance fingers cold No abnormal physical signs in heart Eight months later Home service, symptoms slight

CASE 36—Sergeant — (113181), aged 22 History Teacher Age 17, discontinued football because of palpitation at rather short winded Age 18, joined Territorials August 1914, mobilised Light work as instructor August 1915 to France A month later in a severe engagement since the exertion or excitement more readily produces palpitation and giddiness Wind fair October, admitted Examination No abnormal physical signs Eight months later Light duty in France, no complaints

CASE 37—Sergeant — (31673), aged 38 History Age 17 enlisted Age 23, during South African War army clerk palpitation troublesome, discharged from the Army as D A H Clerk Frequent palpitation with giddiness Fatigued exhausted August, 1914 re-enlisted In France office work frequent palpitation and exhaustion Attacks of giddiness with these symptoms and gasping for breath August 1915 admitted Examination Nervous temperament Apex beat, fifth space in the nipple line Heart sounds normal faint systolic murmur at base only Radial arteries moderately thickened Ten months later Light duty no symptoms

CASE 38—Private — (7571) aged 33 History Shopman Several years palpitation on exertion Short winded August 1914 enlisted In training easily exhausted and rather short of breath October, to France May 1915 to England on exhaustion returned to France in October On marching weakness especially of legs and tightness across front of chest November admitted Examination No abnormal physical signs Six months later Still in hospital no better

CASE 39—Driver — (70058) aged 21 History Labourer Always short winded and subject to palpitation April 1914 enlisted one year before war Palpitation and some shortness of breath August 1914 mobilised In France under fire Palpitation increased and more occurred at least excitement Slight breathlessness December 1915 admitted Examination Nervous temperament Apex beat fifth space internal to nipple line Short soft systolic murmur at apex disappears on standing Five months later Duty in Greece no complaints in letters home

CASE 40—Private — (11071) aged 27 History Carman Age 20 away from work four months before enlistment in 1914 palpitation and weakness symptoms persisted April 1915 enlisted easily exhausted in training November 1915 to France On marching exhaustion and some palpitation and faintness No indigestion January 1916 admitted Examination Apex beat fifth space in the nipple line Heart sounds normal no murmurs Pulse-rate 100 to 110 three days then 80 Six months later Still in hospital much better

ENTERIC-LIKE FEVER IN THE ANGLO-EGYPTIAN SUDAN

ALBERT J CHALMERS M D VICT, F R O S E N G ,
D P H

DIRECTOR, WELLCOME TROPICAL RESEARCH LABORATORIES
AND

NORMAN MACDONALD,

SENIOR BACTERIOLOGICAL LABORATORY ASSISTANT WELLCOME
TROPICAL RESEARCH LABORATORIES KHARTOUM

FEVERS caused by Eberth's bacillus and by the organism paratyphoid A, and to a less extent paratyphoid B are all known to occur in the Anglo-Egyptian Sudan, while Reichardt, in the fourth report of these laboratories, has drawn attention to the presence of peculiar enteric-like fevers clearly separable from the above which are also met with at times. In addition to these varieties, last year we came across a number of cases of an enteric-like fever which were not caused by the ordinary organisms as shown by blood cultures, fecal cultures, and agglutination tests. These cases caused us much trouble until we separated an organism from three of them which by agglutinating with the patient's serum during the later stages of the illness appeared to be the causal factor while its cultural and biochemical reactions indicated that it belonged to the Typhoid Colon Group. As this organism does not appear to have been described, and as its recognition compelled us to devise some scheme by which the bacilli of this group could be readily recognised, we venture to bring forward the following remarks.

Clinical Notes

After a preliminary period of from 1-3 days during which the patient suffers from headache, constipation and malaise, with marked (Chart 1) or slight fever (Chart 2), the febrile attack sets in gradually, being associated with marked constipation and headache and a disinclination for mental or bodily work, and with all the usual signs and symptoms of a mild attack of typhoid fever. An organism could be cultured from the blood, calomel and salines were administered and these relieved the headache but did not appear to influence the course of the fever. Intestinal antiseptics of various descriptions were tried, but they appeared to be useless. The diet was that usually given to a typhoid patient.

After about seven days from the commencement of the true rise of temperature the fever which had gradually risen (Charts 1 and 2) to a maximum lying between 101° and 103° F. subsided quickly and in about another three days fell to normal when the disease ended (Chart 1) or to nearly

CHART 1

This chart illustrates the precursory fever which may occur before the real attack and also a typical attack without a relapse.

The heart, lungs, liver, and spleen remained normal, and except for the usual febrile changes the urine was also normal. Except for headache the nervous system was normal and no skin eruptions were noticed. The cardinal features of the illness were constipation, fever, relatively slow pulse, headache, malaise and a general feeling of illness. The constipation naturally accentuates the inconvenience due to piles if present, which may cause unnecessary alarm if bleeding occurs.

As no organism could be found in the blood it must be concluded that no marked septicæmia could have been present, by which of course it is not meant that large quantities of blood—e.g., 10 c.c.—might not have shown an organism, but unfortunately it did not occur to us to use more than small quantities, 1 to 2 c.c. of blood, as usual well diluted with broth, for this purpose. There being no marked septicæmia, it appeared to us that the fever was mainly toxæmic in nature but it attracted local attention at the time because of its clinical resemblance to a mild attack of typhoid fever.

Since recovery some of the patients whose histories are known to us have kept quite well although more than six months have elapsed. The mortality was nil. The blood serum of these patients, as already stated, did not agglutinate B typhosus or B paratyphosus A or B.

Causal Organism

A minute piece of the feces, obtained in a sterile Petri dish from a patient, was taken up with the tip of a platinum needle and placed in the centre of a plate of Drigalski-Conradi's medium, over which it was distributed by thoroughly rubbing it in all directions by means of a sterile glass spreader. At the end of 24 hours bluish clear dewdrop colonies varying in size and regular in outline could be seen lying between the typical colon colonies. Later these colonies became slightly pink. When similarly plated on Favus medium they appeared at the end of 24 hours as clear colonies regular in outline and varying in size lying among the typical colon colonies.

When these colonies were investigated they were found to be composed of non motile, Gram negative bacilli which fermented lactose in liquid media with the production of acid and gas, and in subcultures produced red colonies on MacConkey's bile salt lactose agar. This organism was agglutinated either completely or nearly completely with the patient's serum in dilution of 1 in 50, and less completely 1 in 100 in one hour after the tenth day of the illness. Eberth's bacillus and the paratyphoid bacilli were not agglutinated though tested repeatedly by microscopical methods. The agglutination reactions, together with the disappearance of the organism from the motions after recovery, induce us to believe that it was the causal factor of this exceedingly mild type of fever which we regard as probably merely toxæmic and producing but slight bodily reactions.

The characters of the organism as grown from three patients were as follows—

Morphology—It is a Gram negative non motile rod measuring on an average about 4 microns in length by 1 in breadth. When treated with carbolfuchsin or other stains it does not show any polar staining, being on the contrary quite homogeneous and having rounded ends.

CHART 2

In Chart 2 there is but slight precursory fever, while the real attack sets in on the fourteenth day and is followed by a relapse.

normal and was followed by a relapse of a more irregular and prolonged nature (Chart 2). When the temperature fell all symptoms gradually disappeared and the patient felt quite well but if the relapse occurred the headache, constipation, &c. returned. At no time was the patient seriously ill and at no time did a relapse produce more than good effects.

Biological characters—It grows best aerobically at 37° C. but it is a facultative anaerobe and can grow quite well at 20-22° C. and at 40° C.

Cultural characters—It grows well on agar-agar at 37° C., forming either isolated, raised, roundish white colonies or an elevated whitish surface growth. It also forms a white growth mainly along the track of the stab, in gelatin which is

not liquefied. On blood serum, which is not liquefied, it produces a growth similar to that on agar agar, but the individual colonies or the confluent growths are larger and more extensive in a given time and are also moister. On potato it forms a yellowish surface growth in 48 hours while in broth it gives rise to a general turbidity without any pellicle formation.

Biochemical reactions.—It forms acid and gas in the following carbohydrate and alcohol media.—*Monosaccharides* Hexoses—glucose, levulose, and galactose, pentoses—arabinose and rhamnose. *Disaccharides* Maltose and lactose. *Glucoside* Salicin. *Alcohols* Trihydric—glycerol, pentahydric—adonitol, hexahydric—dulcitol, mannitol, and sorbitol.

It gives rise to neither acid nor gas in.—*Disaccharide* Saccharose. *Trisaccharide* Raffinose. *Polysaccharides* Dextrin, starch and inulin. *Glucoside* Amygdalin. *Alcohol* Erythrol. *Phenol* Inositol.

With regard to these formations it must be noted that it often failed to ferment lactose when first plated from faeces on Drigalski Conrad's medium and on Fawcett plates, but it never failed in liquid lactose media to produce acid and gas. It was this peculiarity on the solid media which enabled us to pick it out. Sometimes it fails to ferment adonitol, but more generally it produces acid and gas.

It acidified but it did not clot *litmus milk*. It produced *indol* and reduced *nitrates* and *neutral red*, though it failed to give the *Voges Proskauer* reaction.

Serum reactions.—As already stated, it agglutinated either completely or nearly completely with the patient's serum about the tenth day of illness and diluted 1 in 50 and less completely 1 in 100 in one hour. It completely failed to

dilution up to 1 in 5000 and less completely 1 in 10000. An organism giving the reactions of *B. paratyphus* A. recently isolated from a case of fever in Port Sudan, we conclude that it was in good condition.

It also agglutinated with specific paratyphoid B serum but only very partially in dilutions of 1 in 50, and hardly at all in those of 1 in 100 in one and a half hours and was all in greater dilutions. This serum was also shown to be in good condition by agglutinating at the time the laboratory strain of *B. paratyphus* B completely in dilutions extending from 1 in 50 to 1 in 10,000 in one and a half hours.

These agglutinations, in our opinion, showed that the organism was capable of producing agglutinin in the patient's body, and that it was serologically more nearly related to the paratyphoid Gaertner group than to the colon group. On the other hand, the reactions other than agglutinations given above show a close relationship to the colon type. It therefore behoves us to consider the classification of this organism in some little detail.

Classification

As the length of the organism which we are considering is several times greater than its breadth, and as it is not markedly curved in one or more planes, it belongs to Fischer's family *Bacillaceae*, which more or less corresponds to Zopf's *Bacteriaceae* and which probably only contains one genus, *Bacillus* Cohn 1872, as all attempts to differentiate between *Bacillus* and *Bacterium* as separate genera sooner or later break down. The various groups of organisms included in the genus *Bacillus* may be differentiated according to the scheme set forth in Table I, which sufficiently explains itself.

TABLE I.—Genus *Bacillus* Cohn, 1872

agglutinate when tested with polyvalent colon serum of high titre which agglutinated *B. coli* Escherich and was said to be capable of agglutinating several different colon strains, the dilutions employed being 1 in 50 and 1 in 100 and the time being one hour. The serum was in good condition having been tested against the laboratory colon strain.

It agglutinated with specific paratyphoid A serum in a dilution of 1 in 50 after one and a half hours generally only partially but in one instance completely but its agglutination in 1 in 100 dilutions was feeble and in 1 in 1000 and upwards was absent. As this serum completely agglutinated the laboratory strain of *B. paratyphus* A up to 1 in 10,000 in one and a half hours and also completely agglutinated in

Comparing now the characters described above for the organism which we are discussing with the diagnostic tests laid down in this table we conclude that as this organism grows well on ordinary laboratory media without the formation of endospores and is a facultative anaerobe which is fluorescent and does not produce pigment nor liquefy gelatin and does not exhibit polar staining it belongs to the Typhoid Colon Group.

Typhoid Colon Group

The division of this group into subgroups may be accomplished in a more or less natural manner by means of the characters *disaccharides* and *trisaccharides* with the addition of mannitol.

plying these tests we first differentiate a *non-fermenting* group which may be termed the *Alcaligenes Subgroup* using its type *Bacillus alcaligenes*, Petruschky, 1896 (more commonly and less correctly called *B. faecalis alcaligenes*), is ally said to produce neither acid nor gas in sugar media, though it is true that Vourloud has asserted that it can give to slight acidity in laevulose and glycerol

All the other organisms included in the group ferment the monosaccharide glucose, but two subgroups which may be named the *Typhoid Subgroup* and the *Dysentery Subgroup* distinguished by not completely fermenting this sugar, therefore failing to produce gas. They also can and do ferment disaccharides and some of them even the trisaccharide raffinose, producing either acidity or sometimes a slight acidity, and therefore form a natural *partial fermenting division*.

The next step concerns the organisms which may be named the *monosaccharide fermenters*, in which the monosaccharide glucose is completely fermented with the formation of acid and gas, but this large collection of organisms can be further differentiated by means of their action upon a disaccharide lactose. Three disaccharides are in common in the laboratory, and it would appear as though organisms are, as a rule, able to ferment maltose more easily than sucrose and saccharose, and lactose more easily than saccharose.

With regard to lactose two subgroups, the *Paratyphoid aeritner* and the *Morgan I*, fail to ferment it and this can be used as a distinguishing character, while the two subgroups may be differentiated from one another by the fermentation or non fermentation of the alcohol mannitol. A number of organisms, however ferment lactose, producing either acidity only or acid and gas. All these bacilli are closely related to the *B. coli*, Escherich, but some of them may be separated off because they possess the distinguishing feature of a capsule though it must be admitted that no hard and fast line can be drawn between this and the *Colon subgroup*, as there are connecting links in the shape of *B. aerogenes* in which the capsule is difficult to demonstrate, and *B. acidilacti*, both of which may, with convenience, be placed in the *Colon Group*.

This encapsulated group of bacilli has been carefully reviewed by Fricke in 1896, Clairmont in 1902, Perkins in 1904, Abel and Hallwachs in 1913, and Fitzgerald in 1914, and may be termed the *Encapsulated Subgroup*, otherwise known as Friedländer's *B. Pneumoniae Subgroup* or the *Mucos Capsulatus Subgroup*. It is composed of short non motile, Gram negative, encapsulated pleomorphic bacilli which do not form spores, do not liquefy gelatin and which ferment glucose and lactose but as regards the latter sometimes they give rise to acidity only, though more commonly they form acid and gas.

There also appears to be a well-defined group of human intestinal bacilli which ferment glucose, giving rise to acid and gas, but which only partially ferment lactose giving rise to acid only without gas formation, while they do not possess a capsule. These organisms we gather together into the *Weissenberg Subgroup* and refer readers interested therein to the writings of Alexander quoted in the references.

The remaining organisms may be further subdivided by their action upon the trisaccharide raffinose and those which produce acid and gas therein may be collected together into the *Colon Subgroup* with *B. coli*, Escherich, as the type species, while those which fail to ferment this carbohydrate can be placed in the *Entericus Subgroup* with *B. entericus*, Castellani, as the type species.

The distinguishing characters of these various subgroups may be represented in a diagnostic table given below, which shows that the various groups form a natural sequence of—Non fermenters, partial fermenters, complete monosaccharide fermenters, complete disaccharide fermenters, and complete trisaccharide fermenters. Moreover, these form a sort of natural sequence, as may be demonstrated by quantitative estimations of these sugars fermented by the organism which we are considering, which are as follows—

Glucose	35 c.c. of N/20 KHO
Lactose	27 c.c. " "
Raffinose	0.0 c.c. " "

The scheme suggested for the differentiation of these various subgroups is as follows—

Diagnostic Scheme of Typhoid Colon Subgroups

Non fermenters

- A Glucose, lactose, raffinose, and mannitol not fermented
I *Alcaligenes Subgroup*

Partial Fermenters

- B Glucose partially fermented, only acid and no gas produced, lactose, raffinose, and mannitol may or may not be partially fermented—

- I. Motile II. *Typhoid Subgroup*
II Non motile III *Dysentery Subgroup*

Complete Monosaccharide Fermenters

- C Glucose completely fermented with the production of acid and gas—

- I. Lactose not fermented—
(a) Mannitol and raffinose not fermented
IV *Morgan I Subgroup*
(b) Mannitol and sometimes raffinose fermented with production of acid and gas
V *Paratyphoid Gertner Subgroup*

Disaccharide Fermenters

- II Lactose partially fermented with the formation of acid but no gas, mannitol partially or completely fermented, raffinose usually not fermented
VI *Weissenberg Subgroup*

- III Lactose completely fermented with the production of acid and gas—

- (a) Bacilli encapsulated
VII *Encapsulated Subgroup*
(b) Bacilli non encapsulated—
1 Raffinose not fermented
VIII *Entericus Subgroup*

Trisaccharide Fermenters

- 2 Raffinose completely fermented with the formation of acid and gas
IX *Colon Subgroup*

This scheme may be tabulated as set forth in Table II

TABLE II—Typhoid Colon Group

With regard to the organism with which we are at present concerned, it will be noted that as it produces acid and gas in glucose and lactose, while it neither possesses a capsule nor ferments raffinose, it must be placed in the subgroup which we term the *Entericus Subgroup*, which we must now consider in detail.

Entericus Subgroup

As indicated above, this collection of organisms is composed of short, homogeneous, non encapsulated, Gram negative bacilli which produce a whitish non fluorescent growth under aerobic and anaerobic conditions on agar-agar at 37° C and on gelatin which is not liquefied at 20° C, and are capable of producing acid and gas in glucose and lactose but not in raffinose. The oldest organism with which we are acquainted which is capable of being classified in this group is that described by Castellani as *B. entericus*.

As we do not happen to have the Ceylon Medical Reports before us at the present time we are uncertain as to the exact date of the first description, but details with regard to the organism can be found in Castellani and Chalmers (1910) "Manual of Tropical Medicine," first edition, p. 991, or (1913) second edition pp. 1380, 1381, Castellani (1912), *Journal of Tropical Medicine and Hygiene*, xv, pp. 164, 165.

B. entericus is a non motile, Gram negative bacillus which does not liquefy gelatin and produces turbidity in broth with a slight pellicle and gives the indol but not the Voges-Proskauer reaction. It produces acid and gas in glucose, laevulose, galactose, arabinose, maltose, and lactose, but not in saccharose or raffinose, and it can also produce acid and gas in dextrin, dulcitol, mannitol, and sorbitol, but not in adonitol.

The next organism which must be placed in this group is *B. guimari*, which was described by Castellani in the Report of the Advisory Committee for the Tropical Diseases Research Fund for the year 1912 and published in 1913. He isolated the organism from a case of appendicitis and named it after his native Uganda servant of ten years previously who had recently died of sleeping sickness.

B. guimari is a non motile, Gram negative bacillus which produces growths on agar agar, glycerin agar, and serum, resembling the bacilli of the typhoid and dysentery groups and does not liquefy gelatin, but it produces indol and renders litmus milk first acid and then alkaline. It gives rise to acid and gas in glucose, laevulose, galactose, arabinose, rhamnose, maltose, and lactose (the production of gas in this sugar is very slight), but neither acid nor gas in saccharose or raffinose. It also ferments dextrin, salicin, and sorbitol, forming acid and gas, and glycerol, giving rise to only acidity, while it does not ferment inulin, amygdalin, erythrol, adonitol, dulcitol, mannitol, or inositol.

As the organism which we are considering also comes in this subgroup and appears to differ from *B. entericus* and *B. guimari* we give it the name *B. khartoumensis* for purpose of differentiation, and we now compare the reactions of the three bacilli (excluding the group reactions) by means of Table III.

TABLE III—Differential Table of the Members of the *Entericus Subgroup*

Classification	Monosaccharides*				Disaccharides		Polysaccharides		Glucosides		Alcohols						Planted		Other reactions	
	Hexoses		Pentoses																	
Names	Levulose	Galactose	Arabinose	Rhamnose	Maltose	Saccharose	Dextrin	Inulin	Amygdalin	Salicin	Glycerol	Erythrol	Mannitol	Dulcitol	Manuitol	Sorbitol	In vitro	Motility	Urea milk	Total
<i>B. entericus</i> Castellani 1909	A G	A G	A G	—	A G	0	A G	0	—	—	—	—	0	A G	A G	A G	—	0	0	+
<i>B. plicatilis</i> Castellani 1913	A G	A G	A G	A G	A G	0	A G	0	0	A G	A	0	0	0	0	A G	0	0	+	+
<i>B. thartourensis</i> Chalmers and Macdonald 1916	A G	A G	A G	A G	A G	0	0	0	0	A G	A G	0	A G	A G	A G	A G	0	0	+	+

These differences will be referred to in greater detail when we define *B. khartoumensis* and all that need be done at present is to give a diagnostic table.

TABLE IV—*Entericus Subgroup*
Dulcitol

Acid and gas	No change
Adonitol	—
Acid and gas	No change
Dextrin no change	Dextrin acid and gas
1 <i>B. entericus</i>	2 <i>B. khartoumensis</i>

As the reactions given above indicate that the *Entericus Subgroup* is closely related to the *Colon Subgroup* it appears to us to be advisable to consider the latter in greater detail.

The Colon Subgroup

The organisms gathered together to form this subgroup of the Typhoid Colon Group are short, homogeneous, non encapsulated Gram negative bacilli with rounded ends which produce a whitish non fluorescent growth under aerobic and anaerobic conditions on agar-agar at 37° C and on gelatin which is not liquefied, at 20° C and are capable of producing acid and gas in glucose, lactose, and raffinose. It appears to us that the first division of this group should be made as suggested by Smith in 1895 into those organisms which produce and those which do not produce indol. We are aware that much difficulty has been experienced by some workers with the indol test but we refer the reader to Kligler's paper quoted in the references for details as to this test.

It also seems to us that the indol producers can be further subdivided as was pointed out by Durham in 1901, by the fermentation or non fermentation of saccharose, the former subdivision being known as the *Communis Section*, while the latter can be called the *Communis Section*.

Further differentiation may be accomplished by the use of dulcitol as suggested by MacConkey. In this way a diagnostic scheme may be composed as follows—

Fischer's Colon Subgroup

A. Smith's Indol Producing Division

I Durham's *Communis* (Saccharose fermenting) Section

(a) Dulcitol fermenters

1 *B. badullensis*, Castellani, 1913. Isolated from normal motions and cases of chronic enteritis in Ceylon by Castellani.

2 *B. neapolitanus*, Emmerich, 1884. First found in human faeces by Emmerich in Naples and has been found by Castellani in normal motions in Ceylon, by Archibald in the Sudan, by Clemensha in India, and in cow and goat dung in the Sudan by Archibald.

3 *B. oxytocus* (Wyszkowitsch) Flügge 1886. Originally isolated from stale milk and called *B. oxytocus perniciosa* and found in the stools of aeghiostomiasis patients in Ceylon by Castellani, in human faeces in India by Clemensha.

4 *B. paratericus*, Castellani. Found in human faeces in Ceylon by Castellani.

5 *B. pseudocoli*, Castellani, 1909. Found in the motions of patients suffering from aeghiostomiasis in Ceylon.

(b) Dulcitol not fermented

6 *B. coscoroba*. Said to be first described in the *Annales de l'Institut Pasteur* for 1900 as being isolated from an epidemic occurring in a breed of swans called *Cygne de Coscoroba* and described by Clemensha as occurring in human faeces in India and by Archibald in the Sudan.

It will be noted that Durham's *B. communis* really refers to a series of and not to a single organism.

II Durham's *Communis* (Saccharose non fermenting) Section

(a) Dulcitol fermented

1 *B. caricula* Brigger 1885. First obtained by Brigger in human faeces in Europe and found by Clemensha in India.

2 *B. coli* Fischer 1885. This is the well known *B. coli communis*.

3 *B. relapsans* von Fresenburgh 1890. Found first in cheese, later by Archibald in human and bovine faeces in the Sudan by Clemensha in human faeces in India and by Castellani in Ceylon.

- (b) Dulcitol not fermented
- 4 *B. acidilactici* Hueppe, 1884 First found in milk, and subsequently by Clemensha in human faeces in India and by Castellani in Ceylon
- 5 *P. vesiculatus*, Henrici, 1894 Discovered in cheese by Henrici and subsequently found in human faeces in the Sudan by Archibald, and by Clemensha in India
- 6 *B. griffithii*, Castellani Found by Castellani in human faeces in Ceylon

B. Smith's Indol Non Producing Division
I Durham's Communion Section

1 *B. arrogenes* Escherich, 1886, which is often called *lactis arrogenes* and was found in the human alimentary canal in Europe and subsequently in India by Clemensha

2 *B. nasiformans*, Eisenberg 1891, which was first discovered in water but later was recognised in human faeces in India by Clemensha

grown on lactose media forms tubercle-like colonies which are red and white

5 *B. tropicalis* Castellani, 1910, which was first isolated from human faeces in Ceylon

A method of differentiation of these various organisms is set forth in Tables V, VI, and VII

After considering the above analysis it is obvious that if the importance of the non fermentation of the trisaccharide raffinose had not been realised or if that sugar had not been available we should have considered that *B. Thartoumensis* was closely allied to those organisms which are shown in Table VI and especially to *B. schafferi*, which is still very imperfectly known It would, however, have differed from this organism in not clotting milk and in fermenting adonitol We therefore are of the opinion that even when compared against the raffinose-fermenting Colon Subgroup

TABLE V—Escherich's Colon Subgroup

B. coli Norman Hall which is known as *B. coli* Norman Hall and which have brought into the literature. It must not be confused with *B. coli* Sternberg. I refer to the German *B. coli* which is not to be distinguished from *B. coli* Sternberg.

it appears to be a distinct organism and we will therefore not proceed to our deductions on the basis given above

Conclusions

By means of a study of the above schemes and tables of classification it will be seen that *B. Thartoumensis* Chalmers and Macdonald 1916 can be differentiated from the more important members of the Colon Subgroup and that it belongs to the Enteric Subgroup which can be easily distinguished from the other Typhoid Colon Subgroups

As regards the Entericus Subgroup it can be distinguished from *B. grimalii*, Castellani 1913, by not producing acid and gas in dextrin and by producing acid and gas in glycerol, adonitol, dulcitol, and mannitol and from *B. entericus*, Castellani, 1909 by not fermenting dextrin and by producing acid and gas in adonitol and acidity in litmus milk.

We therefore conclude that it is a distinct species and we define it as follows "A short, non motile, homogeneous, non encapsulated Gram negative bacillus with rounded ends, which produces a whitish, non fluorescent growth under aerobic and anaerobic conditions upon agar agar at 37° C, and on gelatin, which is not liquefied, at 20° C and which is capable of producing acid and gas in glucose, lactose, adonitol, dulcitol, and mannitol, but not in saccharose, raffinose or dextrin, and which gives rise to acidity without clot in litmus milk and is also an indol producer. It was isolated from the faeces of persons suffering from an enteric like fever in Khartoum and Omdurman."

It failed to agglutinate with a colon specific serum of high titre but it showed group reactions with high titre paratyphoid A and B specific sera. It is therefore related not merely to the Colon Subgroup but to the Paratyphoid-Gaertner Subgroup and we consider it and possibly the whole Entericus Subgroup to be connecting links between these two collections of organisms.

As it was present in the patients' faeces during the illness and absent after recovery and as it agglutinated with the patients' serum even though we were unable to obtain it from the peripheral blood during the attack, we consider that it was the causal organism of the attacks of enteric like fever, using this term in its broadest sense.

It gives us much pleasure to acknowledge the trouble taken by Dr Papatheodorou, of Khartoum, and Dr Muzhir, of Omdurman, in providing us with material for this paper.

THE GANGRENE OF WAR GASEOUS CELLULITIS OR EMPHYSEMATOUS GANGRENE

BY ALFRED J HULL, F.R.C.S. ENG.,
MAJOR, ROYAL ARMY MEDICAL CORPS.

THE most common form of gangrene met with in the present campaign is an acute infection due to the bacillus of malignant oedema the *Bacillus aerogenes* or *Bacillus perfringens*. The actual cause of gangrene is the presence in the wound of the pathogenic organism which finds a suitable medium in which to grow in the lacerated and devitalised tissue of gunshot wounds. In its most typical and dangerous forms gas gangrene occurs associated with deep wounds, the infection being carried into the tissues by the missile which inflicts the wound. It is therefore a primary and deep infection. Once the wound is infected the occurrence of gangrene is favoured by several conditions: 1. Delay in cleansing the wound and removing the foreign body. 2. Extensive damage to the tissues and the presence of necrosed tissue and blood clot. 3. Interference with the blood supply. The tension produced by the effused blood, the gas, and other products of inflammation produce a vicious circle. 4. The presence of pus-forming organisms. This virulent infection may attack any gunshot wound and forms one of the outstanding dangers to which injuries are subject in war. The complication of an injury by emphysematous gangrene is usually discovered two or three days after the injury but it may begin within a few

hours. A septic wound cannot be considered safe from attack until the wound has become clean and healthy. Cases have occurred in comparatively small and unimportant wounds.

The following forms of the disease are fairly distinct but it must be understood that these varieties are grades of the same disease, passing from one to another. They are grouped here because they form more or less distinct clinical entities requiring entirely different prognoses and treatment.

1 Anaerobic Infection without Gaseous Cellulitis

In this type there is, as yet, no definite spread of cellulitis nor gas in the tissues, but there is discolouration of the skin and gas in the discharge from the wound with characteristic odour. This type, if untreated, goes on to gaseous cellulitis, of which it is really an early stage.

2 Gaseous Cellulitis

This may be local or diffuse. The local variety is fairly amenable to treatment. The infection commences with a local cellulitis with a spread of gas in the tissues, and is usually associated with a deep septic wound. Compound fractures of large pipe bones contribute a high proportion of the cases, and those with fracture of the femur yield the most fatal results. In the local form the cellulitis is limited to the neighbourhood of the wound and apparently has no tendency to spread to the rest of the limb. These cases react well to the simple treatment of multiple incision and some would no doubt recover without special treatment. They account for the majority of successful cases and have made the reputation of several remedies. In the diffuse form the cellulitis involves the whole limb and often spreads to the deep tissues of the limb and the trunk. The skin around the wound is discoloured but the more distant skin is unchanged. The skin may be mottled with blue, purplish, or grey blotches but never presents the bright colour seen in ordinary cellulitis. The limb is very much swollen and is oedematous. The tissues which are permeated by the gas yield a crackling sensation to the touch similar to that found in surgical emphysema. The circulation in the hand or foot is not affected until quite late. The cellulitis appears to be mainly confined to the subcutaneous tissues, the gas penetrating the cellular tissue in advance of the cellulitis. The patient's general condition is soon affected unless the cellulitis is limited to a small area. There is profound toxæmia with a rapid pulse of small volume, the hands and feet are cold and vomiting and diarrhoea often occur. In spite of this the patient may not complain of feeling very ill.

Treatment.—The treatment of the wound does not differ from the treatment of other septic gunshot wounds. The wound should be freely opened and all devitalised tissue excised. The missile should be removed and the wound searched for other septic matter, such as fragments of clothing. Very free drainage in a dependent position should be provided. The cellulitis whether local or general should be treated by numerous incisions into the subcutaneous tissues. In a local case affecting the calf of the leg, three or four incisions several inches in length should be made down to but not through the deep fascia. In addition to these deep incisions half a dozen two-inch incisions through the skin, just entering the superficial fascia should be made. The wound may be dressed with hypertonic saline solution. The infection being an anaerobic one and mainly limited to the cellular tissue the injection of hydrogen peroxide into the cellular tissue at a point proximal to the cellulitis has been undertaken with a view to checking the advance of the disease. About 20 c.c. of a ten volume solution is injected by means of a syringe into the circumference of the limb above the infection. The necessity for this is not established. Collapse, sloughing, and other bad results have followed this treatment. If the infection be localised and the patient's general condition good arm or leg baths of peroxide of hydrogen may be given. Usually the limb is left exposed and continuous irrigation with 5 per cent saline solution employed. If not effectively treated the gaseous cellulitis may advance to a massive gangrene of the whole limb the milder condition passing into the more fatal one with the greatest rapidity. The pulse becoming imperceptible in the extremities of the limb the hand or foot becoming cold and numb are indications for immediate amputation.

3 Localised Gangrene

Around a septic wound a gaseous cellulitis occurs, and bubbles of gas may be detected in the pus coming from the wound. The skin surrounding the wound becomes mottled-purple in colour, and emphysematous crackling can be felt for a short distance beyond the gangrenous area. The case may remain one of localised gangrene or may be overcome by the infection and pass into a case of gangrene of the limb. Extremely foul, dirty fluid containing bubbles of gas, exudes from the wound but typical pus is absent or obscured by the gangrenous discharge. An orange coloured discharge, which stains dressings, is sometimes present. A large number of wounds secrete pus or discharge containing bubbles of gas, although gas is not actually present in the tissues. These wounds recover if treated early by the ordinary method of treatment without extensive operation. In some cases the "gas" has been sucked in owing to movements of the limb. The "gas" is not mixed with the pus in the same way in these cases and the characteristic odour is absent.

Treatment—The devitalised tissues should be excised, and the usual cleansing and drainage operation should be performed on the wound if it has not already been done. Multiple incisions should be made in the emphysematous area. Hypertonic treatment gives good results. The discoloured area should be marked, and if after such treatment it is found to be spreading, amputation should be performed. If the hand or foot is found to be cold and numb and pulseless, it is dangerous to wait until further spread of the local gangrene takes place and amputation should be performed. Sometimes free incision of the calf will restore the circulation of the foot. In such cases the feeble circulation is due to the pressure of the exudate on the vessels under the deep fascia.

Illustrative case of localised gangrene (Fig 1)—Sergeant—, wounded on March 2nd with a fragment of high-explosive shell, entrance wound on the outer side of the leg about middle of fibula, no exit found. Wound dressed at field ambulance and patient arrived at base on March 4th. Leg swollen and painful and oedematous over tibia. Large red patch over middle of calf, extending round to inner side of leg. X-rays showed shell fragment in calf muscles and comminuted fracture of fibula. Entrance wound was excised and shell fragment removed. Incisions were made over the inner side of the leg through extending red patch and in middle of calf. Small quantity of gas and pus escaped and calf muscles felt soft and spongy. The wounds were well irrigated with eusol and tubes were inserted. Temperature 100°F (fell to 98.4°) pulse 110 (fell to 96). The pus showed B. aerogenes capsulatus and streptococci. The patient made a good recovery.

FIG 1

Gas gangrene of calf (localised). Entrance wound on outer side of leg, margins grey and a lighting white area of cellulitis around. Large black patch on tibia. X-rays show area of shell fragment in calf muscles.

Amputation was performed at the level of the leg by the open method. The patient made a good recovery.

4 Massive Gangrene

This corresponds to the distribution of a vessel and may affect part or the whole of a limb. The organisms develop in the part which is rendered anemic by damage to the blood supply of the infected area. Examples of this type may be found in gangrene affecting the gluteal rectus femoris, the adductor, and hamstring groups of muscles.

Illustrative case of massive gangrene (Fig 2)—Private—wounded on March 5th with shrapnel first and second metatarsals comminuted shrapnel passing back, fracturing os calcis and having exit wound in heel. The wound was packed with cyanide gauze and the patient transferred to the hospital on March 7th. The foot was very much swollen and had two bullae on the dorsum. The inner side of the foot was black with grey patches while the ankle joint was red and oedematous. There was a foul smelling discharge containing gas from the wound, which contained B.

5 Gangrene of the Limb

The infection is usually apparent within the first three days after the receipt of the injury. Massive gangrene of the whole limb develops and the limb dies *en masse*. The process is extremely rapid a marked change taking place within a few hours. On several occasions a limb which has been considered healthy in the evening has been discovered to be affected with diffuse gangrene the following morning.

The patient is in a highly toxic condition from absorption from the affected tissue. The temperature is subnormal or only slightly raised. The pulse is rapid and of low tension, the hands and feet are cold and the patient usually suffers from great pain in the limb. The mental condition may remain unchanged, the patient may be alert and uncomplaining, or the dull apathy of toxæmia may be present. The whole

FIG 2

Gas gangrene of foot *en masse*. The dark shading on dorsum and inner side of foot shows the dead gangrenous area in the region of entrance wound while around the exit wound in heel the same is represented. The bullae are seen just below the ankle-joint while the lighter shading extending up the leg marks an area of acute congestion.

limb becomes swollen and tense and no pulse can be felt in the extremity, and the hand or foot is cold and numb. The skin is at first grey white, then mottled grey, green, yellow, purple, and finally black. The infection commences in the neighbourhood of a septic wound, often associated with a septic compound, comminuted fracture. The gangrene spreads with great rapidity the gas diffusing in the cellular tissues, especially beneath the skin and along the course of the great vessels. A crackling sensation can be obtained upon palpation above the actually gangrenous area of the limb, the subcutaneous gaseous cellulitis rapidly spreading to the abdomen or chest. The patient may die of toxæmia before the limb has actually become gangrenous, or even before the gangrenous areas have appeared.

Illustrative case of gangrene of limb—Private—was admitted to a base hospital suffering from a gunshot wound of the left arm. The wound was of the explosive type, probably inflicted at close range. The entrance wound was small the exit wound, over 4 inches in diameter, was lacerated. There was a severely comminuted fracture of the humerus with great destruction of bone and spicules of bone protruded from the ragged sloughing wound. A foul smelling dirty grey coloured discharge containing bubbles of gas exuded from the wounds. Around the wound for several inches the tissues were black and gangrenous, the whole of the limb was intensely swollen, massive gangrene extended up to the axilla, the skin on the inner side being of a mottled green. Above the gangrenous area, extending into the axilla and chest on either side and on to the shoulder above, crackling could be felt on pressure. The outer arm was mottled greyish brown up to within 3 inches of the acromion. The forearm and hand were swollen with tense oedema, mottled greyish green cold and pulseless. The patient's condition was very unfavourable the pulse was small and running the temperature was 100°F, the tongue was dry and furred and the face drawn and anxious. Open ether was administered preceded by atropine gr 1/100 and morphia gr 4. An intravenous saline injection was begun before the operation. The subcutaneous tissue above the gangrenous area was infiltrated with a 10-volume solution of peroxide of hydrogen. A circular incision was made on a level with the lower margin of the axilla on the inner side and about 3 inches below the acromion process on the outer side the incision passing through tissue infected with gaseous cellulitis. The circular incision was carried right down to the bone while the subclavian artery was compressed. After raising the deltoid the humerus was disarticulated at the shoulder. The wound was left open and dressed with saline solution no sutures were used. The patient suffered severely from shock after the operation. Rectal injections

of saline were given during the night. After the first 48 hours' extreme prostration the patient's condition improved. Continuous saline irrigation was instituted, the wound being dressed only with a layer of gauze. A crescentic shaped area of tissue which formed the outer flap became coal black in colour. This piece of tissue demarcated immediately below the acromion and separated eight days later. The wound granulated and rapidly became healthy. It is possible that the sloughing of the flap was due to the infiltration with hydrogen peroxide. This has been omitted in more recent cases with equally good results. The shock would have been less in all probability had the amputation area been infiltrated with local anæsthetic solution.

6 Metastatic Gaseous Gangrene

The above condition has been observed. The gas infection occurs at a part distant from the wound. This exceedingly rare form of infection is presumably a blood infection.

Prevention and Treatment

'The means of preventing gas gangrene will be gathered from its causation. An early cleansing and drainage operation and the removal of missiles, searching examination for concealed septic pieces of clothing, and the efficient drainage of wounds are the primary means of its prevention. The enlargement of apparently clean wounds in cases of fracture of large pipe-bones is advisable where there is any sign of tension and swelling. The interference with the circulation will be obviated by avoiding the use of tourniquets and tight bandages and by efficient splinting which corrects the deformity of fractures. The use of strong antiseptics is to be deprecated, and weak antiseptics will have no effect upon the resistant organisms.

The treatment of gas gangrene is dependent upon two principles. First, the drainage of subcutaneous tissue by means of free incisions in order that the products of inflammation may escape and the spread of infection to the deeper parts may be prevented. The forms of gangrene limited to the cellular tissues will usually react well to this treatment. Secondly, the excision of all necrotic tissue. By excision of all necrotic tissue is meant that irrespective of anatomical consideration the necrotic area must be completely excised and, in the more severe cases, amputation is the only possible mode of effecting complete excision.

When in the presence of compound fracture, gas is found to be issuing from the wound and the skin is becoming grey and mottled and the hand or foot is cold and numb amputation should be performed without delay, as it is of the utmost importance to amputate before the patient is dying of toxæmia. The disease is an extremely fatal one in any case, and calls for recognition and amputation at an early stage. The only form of amputation which can be considered is a direct circular amputation. The amputation should be performed above the infected tissue if possible. Some cases have recovered in which this has not been possible, the gaseous cellulitis having already spread to the trunk. Extension of gas to the trunk does not necessitate amputation. Amputation should in such cases be performed through the gas infiltrated tissues and the remaining infected tissues treated by free incisions. A tourniquet is applied, and in order to obviate shock as much as possible a circular infiltration of all the tissues is made around the whole circumference of the limb with novocaine adrenalin solution.

Several methods of combating the shock of an amputation are available and, since the amputation for gaseous gangrene has to be performed when the patient is in a very toxic condition and very subject to shock, it is essential that one of them be employed. Infiltration of the cauda equina and sacral nerves by introducing 20 c.c. of novocaine solution slowly into the sacral canal through the terminal foramen, the horns of the last piece of the sacrum being the guide to the aperture is a good method and strongly advocated by some surgeons. Blocking the main nerve trunks by injecting them with local anæsthetic solution is a well known method. Spinal anæsthesia is perhaps the best method. I have found the local infiltration of the tissues to be divided with special care in injecting the great nerve trunks a most satisfactory method. No local ill effects or gangrene have followed the infiltration. Saline solution is usually given into a vein during the operation. All the tissues are divided at the level to which the skin retracts after the circular skin incision has been made. No sutures are inserted by this method and free drainage is obtained. The wound is dressed with hypertonic saline solution applied on gauze. After the first few hours constant irrigation is applied to the gauze from an irrigator.

CARDIAC SYMPTOMS FOLLOWING DYSENTERY AMONG SOLDIERS

BY E. B. GUNSON, M.D. F.R.C., M.R.C.P. LOND.
CAPTAIN, R.A.M.C., ATTACHED HAMSTEAD MILITARY HOSPITAL.

THE present paper is based upon notes of 65 consecutive cases of dysentery admitted to the 19th General Hospital, Alexandria, from Gallipoli in October, 1915. The cases were typical of several hundred admitted to the hospital over a period of several months.

Severity and nature of the disease.—Practically all the cases were examples of severe infection, all gave a history of the presence of blood in the stools persisting for several days, the blood still being present on admission in a large proportion of the patients. No bacteriological examination of the stools was carried out, but on clinical grounds 75 per cent were judged to be amœbic, the remainder bacillary in type.

Past history.—There was a history of rheumatic fever in 6 per cent.

Control of the patients.—After admission the worst cases, some of whom were unable to walk or stand owing to extreme exhaustion, were kept in bed entirely. The remainder, including some patients who were still passing blood, often had perforce to rise and walk to the lavatory, a distance of 20 yards from the ward. This necessitated rising, in some cases as often as 30 times during the first 24 hours after admission, and the exertion called for in patients still profoundly weak must be regarded as an important factor in increasing the effect of the disease upon the heart. Even more important, probably, in this connexion is the fact that the majority of the patients continued in the trenches for many days after the onset of dysentery, they often reported sick only when they were completely exhausted.

Drugs.—All the patients received two courses of subcutaneous injections of emetin, in half grain doses twice a day for four days. In the severe bacillary cases anti-dysenteric serum was used. Hemorrhage from the bowel diarrhœa, and pain were treated symptomatically.

Circulatory System

The symptoms and physical signs varied with the severity of the disease.

A. Fatal cases.—There were three fatal cases in the present series, but many others were observed. The circulatory disturbance was profound. The patient was pale. The extremities were cold and clammy. The pulse was small and feeble at times imperceptible at the wrist with a rate of about 100 per minute. Premature contractions (extra systoles) were occasionally met with. Cardiac dilatation followed the extreme enfeeblement of the pulse within 24 or 48 hours in rapidly fatal cases and was accompanied by marked venous congestion especially of the head and neck. In less rapid cases the cardiac dilatation and enfeeblement were delayed for several days after the peripheral circulation had first failed as there were not infrequently marked remissions in the peripheral failure of which the state of the pulse and the cold clammy extremities were evidence. There was usually slight enlargement of the liver. The condition of the patients presented a striking resemblance to that met with in toxic cases of diphtheria. The primary change was apparently a vaso-motor paralysis followed by cardiac dilatation and enfeeblement of heart sounds.

B. Non fatal cases.—This group is of special interest as in not a few cases of so-called "soldier's heart" the onset of symptoms dates definitely from an attack of dysentery.

1. Acute stage.—In some cases a condition approximates to that described above was met with and persisted for several days. In other cases the pulse remained of good strength and no signs of circulatory failure occurred.

2. Convalescent stage.—In practically all cases the symptoms of general weakness and exhaustion met with during convalescence from any severe infectious disease. These patients are first allowed up were present. However, unlike many other diseases convalescence from dysentery is associated in a number of cases with persistent symptoms of circulatory inefficiency such as a sense of exhaustion, dyspnoea, palpitation and giddiness after very moderate exertion which lasts for several weeks and in some cases for several months.

(a) *Patients with mild and transitory symptoms*—In about half the cases it was found that even when the blood had disappeared from the stools, and the temperature had returned to normal the exertion of walking to the lavatory was accompanied by a sense of exhaustion, slight dyspnoea, and palpitation. The symptoms were mild, persisted for a few days only, and were unaccompanied by any sign of cardiac inefficiency.

(b) *Patients with persistent symptoms*—Eleven cases of the present series (17 per cent) presented persistent symptoms of cardiac inefficiency for a long period. The symptoms were still present on the patients' discharge either to England or to convalescent hospitals in Egypt, although on an average 17 days had elapsed since blood had disappeared from the stools and the evening temperature was no longer raised. There was no history of rheumatic fever in any of these cases.

Pulse—The pulse was of full volume and regular. The average rate at rest, was 95 per minute.

Cardiac dullness—The area of cardiac dullness was appreciably increased to percussion in all these patients, transverse cardiac dullness measuring 15 cm and over. The average for patients who presented no symptoms was less than 13 cm. In addition there was usually an increased area of precordial pulsation and in three cases the apex beat was in the sixth space.

Auscultation—The heart sounds were usually sharp and clear. In one or two cases the first sound at the apex was muffled and toneless. A systolic murmur was present in two cases. The liver and spleen were not appreciably enlarged.

Symptoms—*Dyspnoea*—Six patients complained of dyspnoea on walking 30 yards on the level, the remainder developed dyspnoea whenever they climbed a short flight of stairs.

In addition to dyspnoea, all complained of one or more of the following symptoms while walking on the level: Precordial pain, 4 patients; vertigo, 5; palpitation, 2; and sense of exhaustion, 2. The exertion of returning by a ramp, from the dining hall on the ground floor to their ward on the second floor produced such marked symptoms that none of these patients was able to attend the dining hall up to the day of his discharge to England as a convalescent.

Special Treatment

The only drug found to benefit the extreme cardiac weakness met with in the severe cases was adrenalin, and this drug was given in doses of from 5 to 10 minims every four hours subcutaneously. The immediate effect was practically always to increase the volume and force of the pulse and to lessen the degree of pallor or cyanosis for 10 to 15 minutes, while a feeling of well being was induced which often lasted for one hour. In collapsed cases subcutaneous saline injections were of temporary benefit.

Summary and Remarks

1. In a series of 65 cases of dysentery 3 fatal cases all presented signs of considerable circulatory embarrassment. The pulse became extremely feeble and at times was imperceptible at the wrist. The extremities were cold and clammy. In the terminal stages cardiac dilatation occurred and was associated with extreme cyanosis particularly of the face, head and neck. Temporary relief of symptoms was afforded by adrenalin.

2. Of the patients who recovered 17 per cent presented symptoms of circulatory inefficiency persisting into the third week of convalescence when the patients were transferred to England. Dyspnoea, palpitation, precordial pain, vertigo and a sense of exhaustion were the chief complaints. The exhaustion met with in the severe cases was greater than the muscular atrophy and weakness seemed to justify though there was no evidence pointing to organic disease of the central nervous system.

3. The high incidence of persistent cardiac symptoms is a matter mainly to the fact that the majority of the patients continued on duty in the trenches until completely exhausted and the factor was the exertion of walking to the lavatory necessary even during the early stages of the disease owing to the extremities of active service.

4. Cardiac symptoms during convalescence from dysentery are of importance in relation to public health as dysentery is a fairly common disease in a certain number of cases to this day.

5. As a serious case of dysentery adequate rest in bed is essential to the maintenance of cardiac efficiency.

THE RADICAL TREATMENT OF GASTRIC ULCER

By JOSEPH CUNNING, M.B., B.S. MELB., F.R.C.S. Eng.,
SURGEON TO THE ROYAL FREE HOSPITAL, LATE SURGEON
TO THE VICTORIA HOSPITAL FOR CHILDREN AND TO THE
CANCER HOSPITAL.

FOR ulcer of the stomach gastro-jejunostomy has come had its day, and I hope will soon depart with its trail of people who have had bilious vomiting added to their previous misery. That gastro-jejunostomy is marvellous in its effect upon pyloric stenosis from a healed ulcer, or congenital hypertrophic stenosis, is of course true, but in these cases one is dealing with mechanical conditions and not active ulceration. Also it is perfectly true that some cases of gastric ulcer do get well after an anastomosis, but how frequent it is to see some unimproved or relapsing after a few months. The very worst cases of all—those in which the ulcer is embedded in, and excavating the pancreas or some neighbouring organ—I assert are not in the least improved. It is of no use to send a patient out of hospital free of pain, for the rest in bed will procure that, but the patient must be seen at intervals and remain free from pain to speak of cure.

Gastro-jejunostomy has fallen into disrepute for several reasons. 1. Because it frequently fails to relieve the symptoms. 2. Because it is sometimes performed upon a pre-operative diagnosis of ulcer, when the real cause of the symptoms lies elsewhere, as for instance in a diseased appendix. 3. Because it may add to the patient's former troubles bilious vomiting or jejunal ulcer. These conclusions have been gradually enforced upon thinking surgeons, and I am sure that gastro-jejunostomy for the cure of gastric ulcer will be entirely given up.

Sir John Bland-Sutton in his Hunterian lecture, "Ulcers New and Old," has shown that the only certain way of curing duodenal ulcer is by pylorotomy with restoration of the continuity between the stomach and duodenum if possible. For the past six years I have performed excision of simple gastric ulcers in all cases with but few exceptions. The exceptions have been where the ulcer involved surrounding structures, and it seemed the wiser plan to give the patient a chance with the slighter operation of gastro-jejunostomy rather than submit him or her to the more formidable operation of excision of the ulcer. But it was in just these cases that absolutely no relief was obtained, and therefore something further had to be attempted.

Since August, 1914, when I adopted a method which, so far as I know is original I have not met with any case of simple gastric ulcer in which the *stricturess* of gastro-jejunostomy has had to be resorted to. In most cases the gastric ulcer is situated on the lesser curvature or posterior wall. Sometimes the ulcer spreads down both the anterior and posterior walls. In the ordinary case after the gastro-hepatic omentum has been divided, the coronary artery ligatured on either side of the base of the ulcer, it is perfectly easy to remove a small wedge surrounding it and then unite the cut margins of the stomach by two rows of stitches. The nearer the ulcer is to the cardiac end the greater are the difficulties but even then it is merely a question of sufficient retraction and exposure. If the ulcer is in the neighbourhood of the pylorus it is better to perform pylorotomy and then unite the stomach to the duodenum. If the lesion is a saddle-shaped ulcer—that is one perched on the lesser curvature and extending down both the anterior and posterior walls—or as in one of my cases an ulcer 2 inches wide completely encircling the stomach at its middle I prefer to remove that segment of the stomach and then unite the cardiac and pyloric remains. This of course lessens the size of the stomach but as a stomach is a convenience and not a necessity this only ensures that the patient shall not overeat in the future.

But now I come to the real problem and that is the case in which the ulcer is fixed to surrounding structures in such a way that it would seem too dangerous an operation to attempt to remove it. In August, 1914 I had to deal with such a case in which a year previously I had performed gastro-jejunostomy as I considered it unsafe to submit the

patient to so big a risk as excision, for I had found that the ulcer, which was one of the saddle variety, deeply excavated the pancreas with a large area of surrounding infiltration (Figs 1 and 2). However, as the patient had obtained no relief and her life was a constant misery, I agreed to attempt removal. After a thorough exposure

FIG 1

Diagram representing the stomach and pancreas seen through it with the ulcer shaded black where it excavates the pancreas

of the infiltrated part and an attempt at dissecting it out, it looked as if I should endanger the portal vein or the common bile duct and I did not care to face that, so then it struck me that I might detach the stomach from the ulcer by cutting around its margin, sew up the opening in the stomach, and then deal with the ulcer by scraping and cutting away its base in an endeavour to leave a sterile raw surface and not worrying whether it should become adherent to the stomach or not. (Fig 3) As it has turned out, though it is practically certain that the pancreas is adherent to the posterior wall of her stomach, she has had no troubles since the operation. I have seen her recently looking a picture of health. I have put this operation into practice in two cases since with equally good results.

I have had no mortality from the cases of excision of gastric ulcers, though it involves a bigger operation than an ordinary anastomosis, and the results have been good in all. This contrasts well with gastro-jejunostomy which frequently fails to relieve the symptoms.

Gastro-jejunostomy performed upon a pre-operative diagnosis was more frequently done in the early days of the operation, and may still be done by people new to gastric surgery. Unless there is a definite ulcer whose infiltrated margin can be felt, I do not consider there is any justification for assuming its existence, and it is in just such cases if gastro-jejunostomy be performed, that patients have bilious vomiting and possibly a jejunal ulcer added to former troubles. I have had many such cases in which the true cause of the symptoms was a diseased appendix although all the symptoms had been gastric. Some of the patients have had hæmatemesis more than once, but the proof of the cause of their symptoms rests in their immediate restoration to health when the diseased appendix has been removed.

FIG 2

Vertical section through the stomach and pancreas with the ulcer shaded black. A Pancreas, B Gas co hepatic omentum, C Stomach

emptying more quickly it emptied more slowly. Then followed the explanation that the early entry of alkaline duodenal juice into the stomach through the new opening thus diminishing the hyperacidity was the true cause of the occasional good effects. This left it open to

Dr Hertz's query that if this were the whole truth, then why should not regular doses of sodium bicarbonate have an equally good effect? The answer to that was unsatisfactory.

Then another line was chosen, not to explain the rational but to improve the results and arguing that as the cases of pyloric stenosis which had been submitted to gastro-jejunostomy were invariably satisfactory, then the stenosis must have something to do with it, so exclusion of the pylorus was added to it. To my mind the results were no more satisfactory in gastric cases though they certainly were when the ulcer was duodenal. Surely excision of the ulcer is a more sound and practical operation than one based on such poor arguments and uncertain results as gastro-jejunostomy.

That any operation will ensure non-recurrence of an ulcer in the stomach is, unfortunately, not the case. Certainly gastro-jejunostomy will not for in one of my patients a fresh gastric ulcer developed and I had to excise the gastro-jejunostomy to gain access to it. She has since acquired a duodenal ulcer which I have had to operate upon.

Jejunal ulcer is fortunately rare as a sequel but I have known it occur as early as four weeks after gastro-jejunostomy. It may appear as late as seven years after the operation.

If it is true that carcinoma commonly follows upon gastric ulcer there is all the more reason for excision. That this is so I, however, seriously doubt though there are many authorities who assert it. I rarely come across malignant ulcers of the stomach with a long previous history pointing

FIG 3

Posterior view of the stomach after it has been detached from the ulcer showing the latter on the pancreas

to chronic simple ulceration. If chronic ulcer of the leg is to be used as an analogy I think it only proves how rare it is for a simple ulcer to become malignant. In fact the only chronic ulcer I know which frequently becomes malignant is that which occurs in chronic superficial glossitis, which is not on a par with other chronic simple ulcers.

Summary.—That gastro-jejunostomy is unsatisfactory as a method of treatment for gastric ulcer and may even add to the miseries of the patient. That all gastric ulcers can be excised except those which are adherent to important structures in the neighbourhood, and that gastro-jejunostomy is useless for these. When the ulcer is adherent to important structures the stomach can be detached from the base of the ulcer, the opening closed, and the base of the ulcer after being scraped and being now excluded from the stomach will give no further trouble.

Wimpole-street F.

MEDICINAL AND ECONOMIC PLANTS.—The value in education of a study of these plants has been recognised for some time by Dr Jamieson Hurry, of Westfield, Reading. A series of medicinal and economic plants have for several years past been grown in the garden and conservatories at 'Westfield' in order to enable those interested to become acquainted with their appearance. Amongst the plants are tea, coffee, banana, olive, pepper, cinnamon, cotton, flax, hemp, arrowroot, cinchona, capsicum, belladonna, and stramonium. In the case of the plants are arranged specimens of the economic products derived from them and used either for food, for clothing, or for medicine. During each summer the garden and conservatories are thrown open at certain intervals to any who care to avail themselves of the opportunity for a day. Demonstrations of the more important exhibits are given at intervals by Dr Hurry and his assistants.

THE TREATMENT OF HÆMORRHOIDS BY INTERSTITIAL INJECTION

By T BIRD, M.R.C.S., M.A. OXON.

LATE ASSISTANT TO KING EDWARD VII. HOSPITAL, AND CONSULTING AN ESTHETICIST TO GUY'S HOSPITAL AND TO THE EAST LONDON HOSPITAL FOR CHILDREN

ALTHOUGH this treatment has a history of many years, I do not think it has received the attention that its success deserves. It first came to my notice some eight or ten years ago through my old student friend and colleague, the late Sir James Goodhart. Later, requiring some relief from hæmorrhoidal annoyance which was becoming a constant irritation I chose this treatment for the following reasons. The prospect of complete relief in eight or nine visits each taking a quarter of an hour, very slight pain of no duration, and at the same time no interference with my ordinary life and work. The only change that I noticed in the parts treated was an appreciable, but very slight, warmth. It is now some years ago, and I am still perfectly comfortable.

I should like to state that this article was written prior to the appearance in THE LANCET of the articles on the same subject by Mr Arthur S. Morley¹ and Mr F. Swinford Edwards². I have thought it better to leave it as written, for in matters of detail there must necessarily enter the personal equation.

Some critics have suggested that there is a likelihood of return. This has not occurred in my own case or work, but if a part of the pile be left untreated it is likely to increase and I think this must have given rise to the idea of recurrence. There can be no return in the part destroyed and in this opinion I am confirmed by Mr Dudley D'A. Wright, who kindly operated upon me and whose brochure on the subject anyone who means to take up the work should certainly procure.

Pure carbolic acid as an injection into pile tissue was first used about half a century ago in the United States of America but through misuse the practice fell into abeyance. Some 30 years ago it was resumed in a mitigated form by Dr Hoyt of New York. The deviations from his treatment in many hands seem to have caused disappointment perhaps through seeking more rapid or more complete success.

Sir James Goodhart³ speaks very strongly on the operations in vogue, and as I can confirm his remarks both by my own practice and that of over 50 years of anæsthetic work with first class surgeons, I cannot do better than quote him, with the remark that the forecast held out by the surgeon is not always realised by the patient.—

Now why should I thus out of order put in a plea for the more frequent use of injection? I do so because I happen to have seen a good deal of the partial and poor successes of the common operations whereas the results of injection have seemed to me to be uniformly good.

Some years ago I became very dissatisfied with the results of literature. More recently I have known of poor results by the Whitehead operation as well—first because the patient was laid up for several weeks, secondly, because the shock of the operation may be very detrimental, thirdly because even within my own small experience I have known of cases of serious local trouble afterwards invalidating the patient for a long time, fourthly I have many times found a definite membranous stricture at the anus where an operation has been performed, and lastly so many have told me that there has remained, more or less permanently after operation, a state of discomfort in one way or another that was by no means pleasant.

Patients unfortunately do not seek relief until an acute "attack of piles" occurs. This it is as well to palliate in the ordinary way until the inflammation or strangulation is reduced, otherwise the treatment may be painful. The best time for treatment is while the piles are giving no trouble. An acutely inflamed external or strangulated pile may with relief be emptied of blood and then have three or four pigures when introduced the solution stops the bleeding and often relieves the pain immediately.

If a treatment requires no pain at home or hospital for a week or three weeks no anæsthetic or keeping to bed is necessary and no subsequent pain. There is no stretching of the sphincter. It is better to avoid spirit, highly

seasoned dishes, salt, and coffee, otherwise life may go on as usual. In many cases relief is almost immediate. One patient of mine, a clergyman, whose life was a misery said on the third day, after the first pigure, 'I have not had such a two days for six years.' Subsequently in a note he thanked me for his "new life." Riding men, rowing men (I have seen all the seats in a college eight stained with blood) men from the trenches, and drinkers of Gallipoli water seem to be the chief sufferers amongst otherwise healthy men.

It is 50 years ago since I first had a hard external pile when captain and stroke of my college eight. I did not want to leave the boat, and wrote to Mr James Long, professor of surgery at Liverpool to whom I was still indentured, asking what I could do under the circumstances. The reply was worthy of a pupil of Abernethy: 'Row on it until it bursts.' I did, and I hope my crew never noticed the first ten minutes rowing each day, until the parts got warm. The acutely expected event came off, and we made four bumps.

The solution recommended and used by Hoyt consists of equal parts of hazeline and distilled water to which is added 10 per cent of pure carbolic acid, the whole of the acid is not dissolved unless warmed, the bottle must be shaken when the solution becomes turbid from the finely disseminated acid, and is then ready for use. It should not be allowed to run on mucous membrane or skin as in both cases it gives rise to soreness. I have had no trouble through carbolic acid absorption, though I have injected as much as 15 minims at one sitting.

It is not only for hæmorrhoids that the treatment is useful (in my own case there was a polypus in addition to three hæmorrhoids), but also in cases of prolapsus ani. I can look back upon some cases in old people that were treated by astringents which I should now treat in this way rather than with cautery or by incision—the uncomfortable alternatives.

What are the disadvantages of the treatment? There are certainly two—the number of visits and the passage of the anal speculum. The speculum I have found to be best has been Kelly's sphincteroscope both for the first examination and the ensuing treatment but it should always be well warmed before insertion and well lubricated either with vaseline or lubifax, which is more easily washed off with water than vaseline.

The Holborn Surgical Instrument Company have made me a self retaining speculum as Kelly's requires one hand to retain it during the injection by the other. The illustration shows the bulbous extremity which passing through the sphincter retains it in position. The windows vary, the one illustrated is a small speculum for ladies, and allows one to look for fissure or fistula before introducing Kelly's instrument. Another has the window shaped to prevent the mucous membrane in front interfering with the view of the hæmorrhoid.

It is better not to inject a pile near the junction of the mucous membrane and the skin or external to that line before the inner or upper portions have been treated.

External piles (inflamed) should be allowed to subside under appropriate treatment before injection and the patient should be advised against taking wine and spirits and highly seasoned dishes and should be given medicine to produce soft evacuations. A platino-iridium needle not too fine and about an inch and a quarter long is perhaps the best though I use a short stiff needle on a prolongation that fits on to the 'Reconil' syringe as this gives a clear view of the length of the speculum. Care should be taken to keep the needle in the long axis of the bowel and a slight side-to-side motion as the plunger is pressed on tears the interior of the pile and if the needle is kept in for a few seconds there is seldom any bleeding. After an injection or two the pile surface becomes hard so that future injections should be made by the old scars until the pile is completely treated. An ordinary pile condition requires eight or ten pigures, a commercial pile only one or two. A soft, freshly formed hæmorrhoid may be injected with from six to ten minims, these are the ones that bleed most but there is no occasion to apply any styptic the carbolic acid and the hazeline being sufficient to control bleeding. At the first visit I now give preference to injections of not more than three minims especially to

ordinary county asylums, was approaching completion, and it was intended to remove the Council's Pathological Laboratory from Claybury to that establishment. The report of Dr F W Mott, pathologist for the London County Asylums contains interesting particulars of investigations conducted under his direction during the year. An inquiry as to the incidence of mental deficiency among the offspring of the insane in the London County asylums was continued during the year, and altogether the families of 588 insane patients were investigated. According to the reports received from the education authorities it resulted that only 15 (i.e., 2 to 3 per cent) of these had mentally defective children. An investigation was also carried on into the family histories and environment of 60 mentally defective children in London special schools.

Research was conducted by Mr Mann as to the "diagnosis of syphilis by the serum reaction" in order to estimate the incidence of syphilis in various types of the community and as a means of diagnosis in mental disorders, and a detailed summary of the results obtained is included in the Report of the Royal Commission on Venereal Diseases. "Insanity in relation to the ductless glands and reproductive organs" was made the subject of systematic research by Dr Kojima (of Tokio), and previously by Dr Laura Forster. In connexion with hypothyroidism Dr Mott remarks that this condition is more common than is generally supposed in women at the climacteric period. Dr F Sano, superintendent of the Antwerp asylum for acute mental cases up to the time of the German occupation, has since been working in the Claybury laboratory aided by a grant from the National Health Research Committee, and has been investigating the cerebral mechanism of speech. A number of brains, illustrating anatomical defects caused by various pathological lesions having been placed at his disposal, he utilised them to make serial sections and drawings, and to correlate as far as possible the ascertained lesions and peculiarities with the clinical symptoms observed during life. Dr Fisher and Dr Beach have also collaborated with Dr Mott in other research work.

There is much of medical interest in the annual reports of the various asylum superintendents for which we recommend that this volume should be consulted—e.g., statistics as to the etiology of insanity and investigations with regard to dysentery and other diseases prevalent in asylums. Everywhere the male staff has been much depleted owing to the war, and it is greatly to the credit of the medical officers that notwithstanding their enhanced duties they continue to devote much time and energy to the training of nurses and attendants by lectures and demonstrations in preparation for the examination of the St John Ambulance and Medical Psychological Associations.

LIBRARY TABLE

A Text book of Nervous Diseases for Students and Practising Physicians. In 30 Lectures. By ROBERT BRUG, Dozent for Neurology at the University of Basel. Only authorised translation, by CHARLES L ALLEN, M.D., Los Angeles, California. With 111 illustrations in the text. London: William Heinemann. Pp 481. Price 21s net.—The original German edition of this book was reviewed in THE LANCET of March 21st 1914 and it was stated that the originality and suggestiveness of the book would probably be best appreciated by those who already have a fair knowledge of neurology as a whole. The opinion then expressed is confirmed after a consideration of the material in its English guise. The volume is lucid and readable and bears evidence of the clinical experience and erudition of its author, the lecture method of presentation, however suffers from certain disadvantages. The English version bears very much less evidence of being done by a 'hack' translator than has unfortunately been the case with several other American translations that we have had recent occasion to review. The translator knows German and his subject.

The After-treatment of Operations. A Manual for Practitioners and House Surgeons. By P LOCKHART MUMFORD, F.R.C.S. For BA MB BC Cantab. Senior Surgeon, St Mark's Hospital for Cancer, Fistula and other Diseases of the Rectum. Fourth edition. London: Baillière Tindall and Cox. 1916. Pp x+275. Price 5s net.—We are

pleased to see that another edition of this book has been required, for we hold that in many cases the after-treatment of an operation may be almost as important as the operation itself and a work like this is well calculated to be of immense value to those in practice, to resident medical officers, and to senior students. The additions to the present edition are many and important especially the chapter on shock which has been completely rewritten in view mainly of Criles work on the subject. A useful addition is the chapter dealing with gunshot wounds as many have during the war to deal with such wounds who have had little experience previously in this branch of practice.

Studies in Blood Pressure Physiological and Clinical. By GEORGE OLIVER, M.D. Lond., F.R.C.P. Edited by W D HALLIBURTON, M.D. Lond. F.R.S. Third edition. London: H K. Lewis and Co. 1916. Pp 240. Price 7s 6d net.—The author's untimely death prevented him from carrying to completion the present edition of his book. The major part of it was entirely rewritten and ready for the printer and Professor Halliburton took upon himself the task of seeing his friend's book through the press adding a few footnotes where necessary, and reprinting certain omitted chapters from the 1903 edition, with the help of another old friend Dr Alfred Mantle, of Harrogate. This third edition of the late Dr Oliver's work will be welcomed by all exact clinicians, for to these the measurement of arterial tension has become an everyday practice, which is the best testimony to the value of the author's life work.

POOR LAW MEDICAL OFFICERS ASSOCIATION OF ENGLAND AND WALES.—A council meeting was held at 9, Copthall Avenue, E.C., on July 7th, Mr A A Napper being in the chair. The honorary secretary reported that he had been informed that a Poor law medical officer had been very unjustly treated by his guardians. He is the medical officer to a Poor law infirmary which has no accommodation for the treatment of serious operations and when a patient suffering from obstruction of the bowels was brought to him for admission he sent him on to a hospital in the neighbouring city. The friends of the patient were displeased and complained to the guardians, who resolved to pay an outside practitioner a fee of one guinea and deduct it from the salary of their medical officer. The outside practitioner had attended the patient before his admission to the hospital. It can hardly be questioned said the honorary secretary that this is quite beyond the legal powers of the guardians and the matter is now in the hands of the Medical Defence Union.

The council then considered the nomination of officers and members of council for the ensuing year and decided that all the retiring officers and members of council should be recommended for re-election.

The annual general meeting of the association was held later when the report of the council for the preceding year and the balance-sheet were put before the meeting and approved. The officers and members of council who had held office during the last year were then nominated for the next year, and Surgeon General G J H Fyatt C.B. was re-elected President, Dr Major Greenwood honorary secretary and Mr F Greenwood honorary treasurer. Mr Withers Green was reappointed auditor.

After the business of the annual meeting had been concluded the honorary secretary said that he wished to propose a resolution in respect of the action of the Government in reducing the payments for the notifications of infectious diseases from 2s 6d to 1s. Many of our sister societies, he said, have carried resolutions condemning the action and the association should follow the example. He then moved the following—

That this meeting of the Poor law medical officers of England and Wales strongly condemns the recent action of the Government in reducing the fees for the notification of infectious diseases, the consideration of the value of the profession and the great service rendered by it to the Government during the war, the action is excessively mean and it is earnestly hoped that as the war is over these bodies representing the medical profession will take all steps in their power to obtain redress for such losses as they sustain.

This resolution was put to the meeting and carried unanimously.

IODARGOL URASEPTINE

THE Specific of Gonorrhœa,
Acute or Chronic

A Few Clinical Results

Two Cases of Acute Gonorrhœa —

We deem it our duty to draw attention to this action of **Colloidal Iodine**, since it brings about a rapid and certain cure in gonorrhœa and causes a disappearance of the gonococci, without in any way interfering with the integrity of the organs

Drs MIETTE and TRUFFIER.

A Case of Gonorrhœal Follicular Urethritis —

It has seemed to us of some interest to report this case on account of the result obtained, and above all, on account of the means employed for attaining it, for follicular abscesses of gonorrhœal origin, however they may start, always sooner or later acquire chronic symptoms, and we have never so far seen any but surgical treatment leading to a certain cure

The success which has attended our urethral dressings with **Colloidal Iodine** seems to give some promise that the necessity for the radical methods of surgical treatment in cases of urethral folliculitis of gonorrhœal origin may be somewhat reduced

By MARCEL DESCHAMPS late House Physician
Assistant to Dr Bazy of the "Hopital Beaujon" and
JAN PENICHAULT late House Physician of the
Infirmerie Centrale des Prisons

Chronic Urethritis Subacute Urethritis Very Acute Urethritis

We are therefore justified in concluding that **Colloidal Iodine** should be accorded **front rank** among anti gonorrhœal agents, as much on account of the value and rapidity of its action as on account of its absolute harmlessness, which allows us to administer it without the slightest fear of any complication arising owing to its use

Dr GERALD BYLER NANCY
late Interne of the Hospitals

Forms—

Amp of 2 c c Bougies Phials 20 and 45 c c
Ovules

1907—1915.

The Most Powerful of
Urinary Antiseptics.

Uraseptine is a granulated product entirely soluble in water, its bases being **Piperazine**, **Urotropine**, **Helmitol**, **Benzoates of sodium and lithium**, and containing 60 centigrams (10 grs) of active matter to each teaspoonful Dose 2 to 6 teaspoonfuls daily It purifies the urines, and this action is due to its three principal properties

1. IT IS A URINARY ANTISEPTIC.
2. A SOLVENT OF URIC ACID AND OF PHOSPHATES.
3. A MILD NON-TOXIC DIURETIC.

NOTE THE FOLLOWING POINTS —

1 The **Benzoic acid** and the **Benzoates** are transformed in the system into hippuric acid and consequently make the urine acid, which is necessary when the latter is alkaline and ammoniacal

2 Moreover, this acid medium is indispensable for the cleavage of the **Urotropine** (Hexamethylenetetramine), which thus furnishes a certain quantity of Formol, the bacteria destroying properties of which are well known

3 **Helmitol** (anhydro methylen, citrate of Hexamethylenetetramine) possesses not only the property of disinfecting urinary apparatus to a greater extent than Urotropine, but it also possesses sedative anæsthetic properties of utmost value in painful affections

4 Lastly, the **Piperazine** (diethylene diamine) will cause the rapid elimination of uric acid and urates in the form of soluble compounds

URASEPTINE is put up in bottles
containing 9½ oz and 12 oz

LONDON SATURDAY JULY 22 1916

The Prevention and Treatment of Venereal Diseases The Intervention of the State¹

IN the Final Report of the Royal Commission on Venereal Diseases it was recommended that arrangements should be made without delay for providing adequate facilities for the diagnosis and treatment of all persons in the community affected with venereal disease, and a large part of the financial burden which effective measures must imply should be borne, it was said, by the State. The opinion of the Commission was heartily endorsed both by the medical profession and the public. The evidence which came before the Commission proved beyond doubt that venereal diseases—syphilis, gonorrhoea, and soft chancre being so defined—could be controlled and their incidence on the population reduced within narrow limits by early and efficient treatment, but it also appeared that as yet the best methods of diagnosis and therapy are not available for the population generally, with the consequence that venereal diseases inflict a vast amount of preventable suffering upon the community, culminating in the loss of many lives and in the physical ruin of many citizens. The Commission faced the situation squarely by stating that the organisation of arrangements for adequate laboratory facilities and for skilled free treatment should be put in hand at once and in order that the measures taken should have a wide result, and should be unfettered by pecuniary trouble, they advised that these should be entrusted to the councils of counties and county boroughs (among which the Common Council of the City of London was included), and that 75 per cent. of the cost of carrying out the proper schemes should be met from Imperial funds. The Government have decided to accept entirely and immediately the advice of the Commission and Mr LONG, as President of the Local Government Board, has addressed a circular to the public bodies concerned asking for their co-operation, explaining the way in which the gigantic work should be carried out and enclosing the Regulations under which action will be taken. These Regulations have been made under the Health Acts and are issued as an Order of the

Board, who have estimated the conditions of the present war as constituting a case of emergency, which absolves the Board from any necessity of consulting the public bodies in the matter before issuing instructions. The counsel of a strong commission, inspired by unimpeachable evidence, has thus received complete endorsement, and all informed persons will applaud the promptitude of the Local Government Board. There is no doubt whatever that the organisation of scientific measures against venereal diseases will lead immediately to a great reduction in the number of cases and a corresponding alleviation of untold misery, and while this belief is so wide spread that all the local authorities would have given upon their own initiative every encouragement to medical measures undertaken to combat this evil, it is far better that the State, which will find three quarters of the money required, should from the beginning preside over the campaign.

The Regulations of the Local Government Board, made on July 12th, and issued with the circular, direct that the council of every county and county borough shall, subject to the approval of the Board, make arrangements for enabling any medical practitioner practising in the area of the council to obtain, at the cost of the council, a scientific report on any material which the practitioner may submit from a patient suspected to be suffering from venereal disease. They further provide that these public bodies shall prepare and submit to the Board a scheme which ensures the treatment at hospitals or other institutions of persons suffering from venereal diseases, and under which medical practitioners can be supplied with salvarsan or its substitutes. It will therefore be the duty of the councils to proceed at once with the consideration of the steps which they should take in these directions, and with the preparation of a scheme for the provision of the necessary facilities for diagnosis and treatment. In formulating such a scheme they will be much assisted by the memorandum from Dr NEWSHOLME, medical officer to the Local Government Board, on the medical measures which should be taken against venereal diseases. This memorandum is published with the Regulations as a supplement to Mr LONG's circular letter, and contains most practical suggestions as to the best methods by which venereal diseases can be controlled under the conditions constituted in the Regulations. The immediate urgent need, says Dr NEWSHOLME, is that adequate facilities for the diagnosis and treatment of venereal diseases in their early and at all communicable stages should be provided when and where they are absent or deficient. He outlines under three heads the arrangements which will be necessary: (a) The establishment of clinics at hospitals or elsewhere, (b) the supply of salvarsan or its substitutes, and (c) the provision of laboratory facilities for aid in

¹ The Order of the Local Government Board, made on July 12th, 1916, and issued with the circular letter, is published in the *Lancet* of July 22, 1916, p. 153. The Regulations are also published in the *Lancet* of July 22, 1916, p. 153. The memorandum from Dr NEWSHOLME, medical officer to the Local Government Board, on the medical measures which should be taken against venereal diseases, is published in the *Lancet* of July 22, 1916, p. 153.

diagnosis and treatment Under this plan each administrative county and county borough is regarded as a unit for the establishment of a scheme for treatment centres, and the clinic would in the first instance be organised in towns where there is a suitable general hospital, and, when practicable, at hospitals having medical schools attached, as well as at hospitals specially designed for women and children The point is insisted upon both in Dr NEWSHOLME'S memorandum and in Mr LONG'S circular letter that every clinic should be available for the treatment of all comers without distinction as to means or as to place of residence, while the treatment should be given as far as practicable in coöperation with the patient's own doctor These provisions arise directly out of the report of the Royal Commission²

At every clinic the outpatient work, while varying with local circumstances, will certainly be the most important part of the treatment, but accommodation will be required for the treatment of syphilis by salvarsan or its substitutes, and for the care of certain acutely contagious cases whether of syphilis or gonorrhœa, and, further, in the event of surgical complications arising For such cases a small number of hospital beds will have to be made available Experience has shown that syphilis in its infectious stages is best treated by periodic injections of salvarsan or its recognised substitutes, supplemented by courses of mercurial treatment The administration of salvarsan or its substitutes requires special precautions in the selection of patients to whom it may be given, in the technique of administration, and in the frequency of dosage Such matters will demand from the practitioner a certain amount of practical experience, and it is properly laid down that the medical officer of the clinic should possess such personal experience in the diagnosis of venereal disease and in the modern methods for its treatment Salvarsan or its substitutes will be supplied gratuitously if administered by the medical officer of the clinic or by a medical practitioner authorised by him, while the officers' duties will include the giving of demonstrations to medical practitioners on the methods of taking and transmitting material for laboratory diagnosis In this way the level of scientific treatment of venereal diseases will rise rapidly, and it is not foolishly optimistic to expect that our population may soon be largely freed from one of its greatest physical scourges

² The condition that the institutional treatment should be available for the whole community is one to which we attach cardinal importance. The two main difficulties in curing venereal diseases and thus preventing their spread are to ensure the application of patients for treatment at the outset of the disease, and to maintain continued attendance until the doctor certifies that the patient is free from infection. Although gratuitous treatment will not entirely remove these difficulties, we think it will go far to do so. It may be that persons will present themselves for treatment who in the opinion of the medical officer in charge can be satisfactorily treated by their own doctor and who can afford to pay for their own treatment. In such a case we think that the medical officer might properly refer the patient to a private practitioner. But if the patient is unwilling there should in our opinion be no refusal to treat him at the institution. *Report of the F.S.S. Committee on Venereal Diseases, Dec. 1915.*

Aortic Incompetence

AN efficient heart is desirable in any walk of life. To the soldier it is a necessity, and the daily experience in camp and on the field is showing that the civilian standard of efficiency is often too low for the fighting man. The experienced examiner of recruits is able to weed out most cases of damaged valves, but his tests are at present insufficient to detect muscular inefficiency which may give rise to trouble later. The truth of this is shown by an inquiry, which we publish this week into the various conditions which lead men on active service to report sick with symptoms suggesting heart disease. Among 90 consecutive cases so reporting Captain JOHN PARKINSON, R.A.M.C., found only 28 of valvular disease of all kinds, while in 40 others who had definite cardiac symptoms no evidence of any damage to the valvular mechanism could be detected. In another series of cases Captain E. B. GUNSON, R.A.M.C., indicates the rôle which dysentery may play as one of the varied factors in the production of muscular cardiac inefficiency. Numerically infrequent, then, as valvular disease may be in the recruit who has passed a careful clinical examination, the importance of aortic incompetence must not be entirely overlooked. In eight soldiers who complained to Captain PARKINSON of giddiness and faintness six were found to have incompetent aortic valves and in one of these syncope had occurred.

In the quiet and spacious times of peace the victims of aortic incompetence may get along well enough. The strain of warfare both for the combatant and the non-combatant evidently has a specially malign influence upon this form of cardiac lesion and gives to the well-worn topic of digitalis treatment a new and pressing interest. The use of digitalis in aortic incompetence has been discussed at length by numerous authorities, foremost amongst whom was the late Dr MILLER FOTHERGILL, and Sir CLIFFORD ALLBUTT, Dr MITCHELL BRUCE, Sir JAMES MACKENZIE, Dr GEORGE BALFOUR, and others have considerably added to the clinical evidence as to when the drug should be given or withheld. It has been strongly urged that the tone of the heart must be constantly watched, for digitalis has the power of intensifying tone and of moderating distensibility. Careful discrimination, however, has to be employed in determining whether stimulation to the muscular power of the heart is required. Needless to say the employment of any drug, especially of the digitalis group, simply because a murmur is heard on auscultation cannot be too strongly deprecated. Digitalis itself is a potent remedy with a tendency to a cumulative action and its indiscriminate use may be attended with evil consequences. Are there, then, any definite rules that can be laid down for the guidance of practitioners in regard to prescribing digitalis in cases of aortic regurgitation?

In the first place, it must be insisted on that aortic regurgitation may exist without giving rise to any symptoms, the condition only being accidentally discovered, as, for instance, in examination for life assurance, and most physicians could mention cases in their own experience of individuals who had led most active lives without in the least being aware that they were the subjects of a grave cardiac lesion. One of Captain PARKINSON'S cases, a man of 40, who had served 16 months, including six at trench work, was found by chance to have a to and fro aortic murmur. Such cases are generally young subjects, often with a history of rheumatic fever in childhood. In other words, a stationary lesion is present with good compensation. A very different condition holds when the aortic regurgitation is the result of degenerative processes—that is to say, a progressive lesion. Some patients live to their ordinary expectancy, and some even beyond with incompetence of the aortic valves, and without ever having had a dose of digitalis, and some interesting cases of this kind were recorded by Dr SYMOUR TAYLOR in our columns last week. But such instances are exceptions to the well recognised fact that aortic regurgitation is the most serious of all valvular lesions. As long as the compensation continues efficient no treatment is, of course, necessary, but if evidences of failure of the cardiac reserve force begin to assert themselves then systematic treatment is urgently demanded. The most important therapeutical measure is rest, and the extent to which this must be insisted on varies with each individual case. In some instances only slight modification of the patient's usual life is required, such as the avoidance of hurry and of undue mental exertion. Irritability, apprehensiveness, worrying over unimportant details, are all symptoms of want of an efficient circulation through the brain, and if the nervous system can be soothed, bromides being useful for this purpose, improvement may occur without the necessity of employing other drugs. If, however, not only the cardiac "reserve" force but the "rest" force also is impaired, then confinement to bed is necessary, and some modification of diet may be requisite. But in these cases, as in other forms of early heart failure this paraphrase holds good. "And now abideth diet, drugs, and rest, these three, but the greatest of these is rest." In cases of aortic regurgitation the avoidance of sudden or extreme exertion is all important, for if such precautions are not taken sudden death is not uncommon. The victims of aortic incompetence must be rigidly excluded from the army.

Ne quid nimbis"

THE SUPPLY OF PETROL TO MEDICAL PRACTITIONERS.

THE apportionment of petrol to those members of the medical profession who have duly complied with the requirements of the Petrol Control Committee is now proceeding. The medical profession is receiving the first attention, being given the *pas* of all other users, commercial and private. The apportionment warrants, which are being sent out, should be returned as directed, together with the necessary remittance for the amount of the new duty—in the case of medical men 3d a gallon—and in return a licence will be received, covering a period of six months, authorising the holder of the licence to purchase petrol during each month up to an amount not exceeding the quantity stated on the licence. The distribution does not appear to be based on any particular average of the amount asked for by practitioners in their returns. In one case brought to our notice 70 gallons a month were asked for, and the amount allotted is 50 gallons. In another case 25 gallons were asked for and 24 gallons are allotted. The inference, therefore, is that an effort has been made by the authorities to meet the reasonable requirements of the profession by weighing up each demand so far as is possible, though a very wasteful engine may upset all estimates of reasonable need. If the majority of the profession have been treated on the lines of the medical man who asked for 25 gallons and got 24, the reasonable requirements of the profession will have been met. The new regulations come into force on August 1st, after which date no one can get a supply of petrol unless he is in possession of a special licence for this purpose, and produces the licence for endorsement on each occasion of taking in a supply. There are heavy penalties for any infringement of the regulations, either on the part of the buyer or the seller. So far so good, but there is a weak point in the scheme. It is that the Government do not intend to take over the supply and the distribution of the spirit, so that there is a possibility, and even a great probability, that medical men in the remote country districts, possessing licences to obtain petrol, may find their local dealers without a supply. It would be wise for practitioners so situated at once to take out their licences and forthwith to give their orders to their local garages for the full amount of their monthly requirements, and if they find, as the months go round, that they can do with less than they are authorised to obtain, they should reduce their orders accordingly, to the benefit of the community generally. Those practitioners who did not make the return called for by the Petrol Control Committee will find their supplies cut off altogether unless they quickly take steps to repair the omission.

THE METROPOLITAN WATER-SUPPLY

COMPARED with the previous months April was a relatively dry one the mean rainfall for the Thames basin being 1.19 inches, or 0.51 inch below the average mean rainfall for that month during the previous 33 years. The samples of water collected at the different works were, generally speaking,

Lambert, one of the two women student medical
officers attached to the Local Government Board with
special rank, has been appointed dean of this depart-
ment for the year beginning at the College.

clear, bright, and free from suspended matter. The results of chemical examination employing the albuminoid nitrogen, permanganate, turbidity, and colour tests showed that the raw Thames and Lee waters improved in quality during the month. The same was true in regard to the raw New River water, except a deterioration shown by the albuminoid nitrogen test. The filtered waters improved generally, though there were exceptions in regard to particular tests. Making a comparison with the 1915 averages, the raw waters yielded results better than their respective averages, as judged by the albuminoid nitrogen, permanganate (in both cases New River excepted), turbidity, and colour tests. The filtered waters fell back to a slight extent on the 1915 averages judged by the usual tests. All three raw waters, however, contained less bacteria than their respective averages, with the exception again of New River water, which contained more, while the filtered waters, generally speaking, yielded not unsatisfactory results. In April 93.7, 81.2, and 0.0 per cent of the samples of raw Thames, Lee, and New River respectively contained typical *B. coli* in 1 c.c. (or less) of water examined, while of the filtered water samples derived from these sources 96.3, 94.4, and 93.0 per cent contained no typical *B. coli* even in 100 c.c. These results show a remarkable state of bacteriological purity.

DIARRHŒA AND ENTERITIS IN RELATION TO PRIVY MIDDENS

In his annual report for 1915 Dr H. Peck, the medical officer of health for Chesterfield rural district, calls attention to the high diarrhœa death rate in the district. The number of deaths at all ages from this disorder during the year under review was 43, as compared with 28 in the previous year, the rate per 1000 being 0.64 as compared with the decennial average of 0.79. Dr Peck states that this rate is always higher in Chesterfield rural district than in England and Wales, where the average rate for the ten years ending 1913 was 0.52, and, in his opinion, the remedy lies in converting all the privies in the more populous parts of the district into water closets. As an example of what may be done in this direction he instances Speedwell, Staveley, where the conversion of the privies in 1911 resulted in the reduction of the death rate by half, a condition that has continued to the present time. This is certainly a very striking result, though we gather from the Chesterfield rural district annual report for 1913 that the population of the area in question was only 894 and care must therefore be exercised in drawing general deductions from such relatively small figures. Apparently in the two parishes of Herth and Temple Normanton the average diarrhœa rate is high, these parishes having lost annually during the last ten years 2.68 and 2.00 per 1000 respectively of their populations from this preventable disease. The high average rate in these parishes is stated to be due to the presence of the insanitary colliery villages of Holmewood and Bonds. Main the houses of which are built in rows with privy middens flanked by coal houses placed in an almost continuous line between every two rows. Sutton cum Duckmanton, containing Arkwright Town built on similar lines and Killamarsh, have also high rates. Dr Peck advocates the carrying out of an almost universal conversion of privies in the southern parishes of the district. The available water

supply is at present insufficient to meet the needs of the water closets which would replace the privies were such a scheme of conversion carried out, and Dr Peck urges the necessity of increasing the storage capacity of the southern reservoirs and suggests that, as the interests of Chesterfield rural district and Clay Cross urban district might possibly conflict, it would be desirable that the two councils should take joint action in the matter. We hope the authorities concerned will give careful consideration to the recommendations contained in Dr Peck's annual report with the view of having these much needed sanitary reforms carried out as soon as the restoration of peace permits of the further expenditure of public money.

INDIA'S VITAL STATISTICS

How fundamentally the health conditions of India differ from those of other countries of the world is brought out in a report issued by the Department of Statistics. This analyses the health returns compiled by the Indian sanitary authorities. It shows, for example, that whereas in practically all European countries there is an excess of female births over male births, in India the contrary is markedly the case, the mean number of male births in India, taking the female births as 100, varying from 126 in the North West Frontier Province to just short of 101 in Coorg. Again, both the birth and the death rate in India are extraordinarily high as compared with Western countries. Like the West India has a falling death rate, the India ratio having gone down from 33 deaths per 1000 per annum in 1910 to just under 29 per 1000 in 1913. On the other hand unlike Europe, India still has a rising birth rate, the India ratio of births per 1000 of the population having increased from 35 in the quinquennial period 1886-90 to 39 in 1913. As regards provinces, the return shows Delhi as the most unhealthy, with a death rate of close upon 40 per 1000 in 1913, the year taken for review, while Madras is able to claim to be the most healthy, having had in the same period a death rate of a little over 21 per 1000.

RENAL GLYCOSURIA

FROM time to time cases have been recorded in which a small amount of sugar is present in the urine and yet the blood contains only a normal amount of sugar. The patient remains in good health and none of the symptoms of diabetes are present. The body has lost none of its power of assimilating carbohydrate, and diet usually has little influence on the glycosuria. The latter is held to be due to an abnormal permeability of the kidney to sugar, and is therefore termed renal glycosuria or—less correctly—renal diabetes. In the *Johns Hopkins Hospital Bulletin* Dr D. S. Lewis and Dr H. O. Mosenthal have published an important paper on the subject in which they report the following case. A man aged 29 years who appeared to be in the best of health, came under observation. Six weeks previously he saw his medical attendant for backache, and glycosuria was found. The former quickly disappeared but the latter persisted in spite of carbohydrate restriction. The urine was of specific gravity 1035 and contained sugar but was otherwise normal. The amount of sugar in the urine varied from 0.8 to 2 per cent while the sugar in the blood varied a little from the normal, 0.03 per cent. The glycosuria

was considerably reduced by restricting the carbohydrates in the diet, but could be made to disappear only by six days starvation, and reappeared on only a minimum amount of food. The amount of sugar passed was below 12 grammes daily when carbohydrate was restricted, but reached 30 grammes when the carbohydrate was increased. The question of the relation of renal glycosuria to diabetes is a difficult one and cannot be answered at present. The recorded cases are few and they have not been followed for a sufficient time to ascertain whether diabetes develops. Dr Langdon Brown has recorded the case of a man, aged 40 years and in good health, who was rejected for life assurance four years previously because the urine contained sugar. His blood contained only 0.04 per cent of sugar. Yet he was not a typical example of renal glycosuria, as the amount of sugar in the urine on one occasion rose to 9 per cent. Later he lost weight and developed symptoms of neuritis. The blood sugar was found to have risen to 0.142 per cent. He thus passed from hypoglycæmia to hyperglycæmia. Evidently ordinary diabetes was developing from a condition of renal glycosuria.

SPONTANEOUS RUPTURE OF THE MALARIAL SPLEEN

In the *Journal of the American Medical Association* Dr W. E. Leighton, of St. Louis, and Dr F. Voeller, of Chicago, have reported from the 23rd General Hospital of the British Expeditionary Force, France, a case of spontaneous rupture of the malarial spleen—an occurrence which has been seldom recorded. An artilleryman was admitted in August, 1915, with the following history. He went to India in February, 1912, and in August had an attack of dysentery which lasted a few weeks. After recovery he suffered from chills which recurred regularly one during the day and another during the night. After two days treatment they disappeared and he remained well until October 1914 when they recurred while he was on a transport returning to England. He again recovered under a few days treatment. While at the front in France after a severe bombardment he had some nervous trouble for several days. On August 13th, 1915, he was taken ill with chills, fever, headache and pains in the abdomen. There was no history of any injury. He was put to bed for six days at a casualty clearing station and felt better. He was then removed to the 23rd General Hospital. While on the train he was seized with severe pains in the epigastrium, which extended later over the whole abdomen. On admission the temperature was 97.1. He was emaciated and anæmic. The respirations were slow but shallow, the right chest moved less than the left and its lower part showed an area of dullness extending 1 inch above the nipple. Over this area vocal fremitus and breath sounds were diminished. The left chest showed normal breath sounds but was hyperresonant. Cardiac dullness was to the left of the nipple line and the apex beat was one inch from this in the fourth interspace. The abdomen was slightly distended but soft and there was no muscular rigidity. The region of the gall bladder was very tender especially towards the epigastrium and there was a tenderness of the appendix region. Acute attacks of pain simulating biliary colic but extending to the left upper hypochondriac region occurred. The temperature ranged from 101 to 102. During the night of August 25th there was a severe attack

of pain in the epigastrium, the temperature fell to 97.4° and the pulse rose to 120. The patient was collapsed. Exploratory laparotomy was performed in the right upper quadrant of the abdomen. Much old clotted blood and also dark fluid blood appeared. There were adhesions between the parietal peritoneum and the liver, but no gall stones were felt. The spleen was enlarged and soft and the omentum was firmly adherent to its convex surface. The adhesions were not broken down and the abdomen was closed, drainage being provided. Convalescence was interrupted by an attack of pneumonia, and after the crisis chills occurred and the malarial plasmodium was found in the blood. Though no bleeding point was found at the operation the evidence was clear that the source must have been a rupture of the enlarged spleen which led to the formation of adhesions.

ROYAL MEDICAL BENEVOLENT FUND AN EMERGENCY APPEAL

Dr Samuel West, as honorary treasurer of this Fund, gratefully acknowledges the receipt of four large donations in response to the appeal which appeared in *THE LANCET* in July, besides smaller sums. The donations, each of £100, are from Dr A. Whitfield, Miss Helen Hall, Sir John Tweedy (President of the Fund), and Mr Hurry Fenwick. At the meeting in the month of May the committee had a balance of only £27 0s 1d, in June a deficit of £16 3s 5d, and in July a balance of £24 13s. Grants in relief were made in May of £197, in June of £190, and in July of £280 15s, £667 15s in all, the amount expended thus exceeding the receipts by no less than £632 5s 4d. The need of liberal and immediate relief is obvious, and subscriptions should be sent to Dr Samuel West, at 11, Chandos street, Cavendish square, W. We refer our readers to a letter from Dr West published in another column.

We deeply regret to learn of the death of Sir Victor Horsley, which occurred in Mesopotamia at the beginning of this week. In him we have lost one of the first exponents of British surgery, a great physiological discoverer, and a forceful and generous personality. His death will be universally deplored.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

MEETING OF COUNCIL

A QUARTERLY meeting of the Council was held on July 13th. Sir W. WATSON CHEYNE, the President, being in the chair. Sir W. Watson Cheyne was re-elected President of the College and Mr Harrison Cripps and Mr Charters Symonds were elected Vice Presidents for the ensuing collegiate year.

The PRESIDENT announced the result of the recent election of members of Council. Mr Haslam and Mr Johnson were introduced, and they made declarations in the terms of the oath prescribed by the Charter of 1800 and took their seats in the Council. Mr Charters Symonds, re-elected on a previous occasion, was also introduced.

It was resolved to grant jointly with the Royal College of Physicians of London Diplomas in *Prædicta* to three successful candidates.

The PRESIDENT reported on behalf of the Council in the Vice-Presidents that as requested by the Council in July 1915 they had on Dec. 1 and 15 and 6th and 13th July 1916 held conferences with the Board on the part of the special foreign law medical officers and that as a result of these conferences it was proposed to

clear, bright, and free from suspended matter. The results of chemical examination employing the albuminoid nitrogen, permanganate, turbidity, and colour tests showed that the raw Thames and Lee waters improved in quality during the month. The same was true in regard to the raw New River water, except a deterioration shown by the albuminoid nitrogen test. The filtered waters improved generally, though there were exceptions in regard to particular tests. Making a comparison with the 1915 averages, the raw waters yielded results better than their respective averages, as judged by the albuminoid nitrogen, permanganate (in both cases New River excepted), turbidity, and colour tests. The filtered waters fell back to a slight extent on the 1915 averages judged by the usual tests. All three raw waters, however, contained less bacteria than their respective averages, with the exception again of New River water, which contained more, while the filtered waters, generally speaking, yielded not unsatisfactory results. In April 93.7, 81.2, and 0.0 per cent of the samples of raw Thames, Lee, and New River respectively contained typical *B. coli* in 1 c.c. (or less) of water examined, while of the filtered water samples derived from these sources 96.3, 94.4, and 93.0 per cent contained no typical *B. coli* even in 100 c.c. These results show a remarkable state of bacteriological purity.

DIARRHŒA AND ENTERITIS IN RELATION TO PRIVY MIDDENS

In his annual report for 1915 Dr H. Peck, the medical officer of health for Chesterfield rural district, calls attention to the high diarrhœa death rate in the district. The number of deaths at all ages from this disorder during the year under review was 43, as compared with 28 in the previous year, the rate per 1000 being 0.64 as compared with the decennial average of 0.79. Dr Peck states that this rate is always higher in Chesterfield rural district than in England and Wales, where the average rate for the ten years ending 1913 was 0.52, and, in his opinion, the remedy lies in converting all the privies in the more populous parts of the district into water closets. As an example of what may be done in this direction he instances Speedwell, Staveley, where the conversion of the privies in 1911 resulted in the reduction of the death rate by half, a condition that has continued to the present time. This is certainly a very striking result, though we gather from the Chesterfield rural district annual report for 1913 that the population of the area in question was only 894 and care must therefore be exercised in drawing general deductions from such relatively small figures. Apparently in the two parishes of Heath and Temple Normanton the average diarrhœa rate is high, these parishes having lost annually during the last ten years 2.68 and 2.00 per 1000 respectively of their populations from this preventable disease. The high average rate in these parishes is stated to be due to the presence of the insanitary colliery villages of Holmewood and Bonds Main the houses of which are built in rows with privy middens flanked by coal houses placed in an almost continuous line between every two rows. Sutton cum Duckmanton, containing Arkwright Town built on similar lines and Killamarsh, have also high rates. Dr Peck advocates the carrying out of an almost universal conversion of privies in the southern parishes of the district. The available water

supply is at present insufficient to meet the needs of the water closets which would replace the privies were such a scheme of conversion carried out, and Dr Peck urges the necessity of increasing the storage capacity of the southern reservoirs and suggests that, as the interests of Chesterfield rural district and Clay Cross urban district might possibly conflict, it would be desirable that the two councils should take joint action in the matter. We hope the authorities concerned will give careful consideration to the recommendations contained in Dr Peck's annual report with the view of having these much needed sanitary reforms carried out as soon as the restoration of peace permits of the further expenditure of public money.

INDIA'S VITAL STATISTICS

How fundamentally the health conditions of India differ from those of other countries of the world is brought out in a report issued by the Department of Statistics. This analyses the health returns compiled by the Indian sanitary authorities. It shows, for example, that whereas in practically all European countries there is an excess of female births over male births, in India the contrary is markedly the case, the mean number of male births in India, taking the female births as 100, varying from 126 in the North West Frontier Province to just short of 101 in Coorg. Again, both the birth and the death rate in India are extraordinarily high as compared with Western countries. Like the West India has a falling death rate, the India ratio having gone down from 33 deaths per 1000 per annum in 1910 to just under 29 per 1000 in 1913. On the other hand, unlike Europe, India still has a rising birth rate, the India ratio of births per 1000 of the population having increased from 35 in the quinquennial period 1886-90 to 39 in 1913. As regards provinces, the return shows Delhi as the most unhealthy, with a death rate of close upon 40 per 1000 in 1913, the year taken for review, while Madras is able to claim to be the most healthy having had in the same period a death rate of a little over 21 per 1000.

RENAL GLYCOSURIA

From time to time cases have been recorded in which a small amount of sugar is present in the urine and yet the blood contains only a normal amount of sugar. The patient remains in good health and none of the symptoms of diabetes are present. The body has lost none of its power of assimilating carbohydrate and diet usually has little influence on the glycosuria. The latter is held to be due to an abnormal permeability of the kidney to sugar, and is therefore termed renal glycosuria or—less correctly—renal diabetes. In the *Johns Hopkins Hospital Bulletin* Dr D. S. Lewis and Dr H. O. Mosenthal have published an important paper on the subject in which they report the following case. A man aged 29 years who appeared to be in the best of health, came under observation. Six weeks previously he saw his medical attendant for brachache and glycosuria was found. The former quickly disappeared, but the latter persisted in spite of carbohydrate restriction. The urine was of specific gravity 1035 and contained sugar but was otherwise normal. The amount of sugar in the urine varied from 0.8 to 2 per cent while the sugar in the blood varied a little from the normal 0.03 per cent. The glycosuria

was considerably reduced by restricting the carbohydrates in the diet, but could be made to disappear only by six days' starvation, and reappeared on only a minimum amount of food. The amount of sugar passed was below 12 grammes daily when carbohydrate was restricted, but reached 30 grammes when the carbohydrate was increased. The question of the relation of renal glycosuria to diabetes is a difficult one and cannot be answered at present. The recorded cases are few and they have not been followed for a sufficient time to ascertain whether diabetes develops. Dr Langdon Brown has recorded the case of a man, aged 40 years and in good health, who was rejected for life assurance four years previously because the urine contained sugar. His blood contained only 0.04 per cent of sugar. Yet he was not a typical example of renal glycosuria, as the amount of sugar in the urine on one occasion rose to 9 per cent. Later he lost weight and developed symptoms of neuritis. The blood sugar was found to have risen to 0.142 per cent. He thus passed from hypoglycaemia to hyperglycaemia. Evidently ordinary diabetes was developing from a condition of renal glycosuria.

SPONTANEOUS RUPTURE OF THE MALARIAL SPLEEN

In the *Journal of the American Medical Association* Dr W. E. Leighton, of St. Louis, and Dr F. Moeller, of Chicago, have reported from the 23rd General Hospital of the British Expeditionary Force, France, a case of spontaneous rupture of the malarial spleen—an occurrence which has been seldom recorded. An artilleryman was admitted in August, 1915, with the following history. He went to India in February, 1912, and in August had an attack of dysentery which lasted a few weeks. After recovery he suffered from chills which recurred regularly, one during the day and another during the night. After two days treatment they disappeared and he remained well until October 1914 when they recurred while he was on a transport returning to England. He again recovered under a few days' treatment. While at the front in France after a severe bombardment he had some nervous trouble for several days. On August 13th, 1915, he was taken ill with chills, fever, headache, and pains in the abdomen. There was no history of any injury. He was put to bed for six days at a casualty clearing station and felt better. He was then removed to the 23rd General Hospital. While on the train he was seized with severe pains in the epigastrium which extended later over the whole abdomen. On admission the temperature was 97.1. He was emaciated and anæmic. The respirations were slow but shallow. The right chest moved less than the left and its lower part showed an area of dullness extending 1 inch above the nipple. Over this area vocal fremitus and breath sounds were diminished. The left chest showed normal breath sounds but was hyperresonant. Cardiac dullness was to the left of the nipple line and the apex beat was one inch from this in the fourth interspace. The abdomen was slightly distended but soft and there was no muscular rigidity. The region of the gall bladder was very tender especially towards the epigastrium and there was tenderness of the appendix region. Acute attacks of pain, simulating biliary colic but extending to the left upper hypochondriac region occurred. The temperature ranged from 101 to 102. During the night of August 25th there was a severe attack

of pain in the epigastrium, the temperature fell to 97.4° and the pulse rose to 120. The patient was collapsed. Exploratory laparotomy was performed in the right upper quadrant of the abdomen. Much old clotted blood and also dark fluid blood appeared. There were adhesions between the parietal peritoneum and the liver, but no gall stones were felt. The spleen was enlarged and soft and the omentum was firmly adherent to its convex surface. The adhesions were not broken down and the abdomen was closed, drainage being provided. Convalescence was interrupted by an attack of pneumonia, and after the crisis chills occurred and the malarial plasmodium was found in the blood. Though no bleeding point was found at the operation the evidence was clear that the source must have been a rupture of the enlarged spleen which led to the formation of adhesions.

ROYAL MEDICAL BENEVOLENT FUND AN EMERGENCY APPEAL

Dr Samuel West, as honorary treasurer of this Fund, gratefully acknowledges the receipt of four large donations in response to the appeal which appeared in *THE LANCET* in July, besides smaller sums. The donations, each of £100, are from Dr A. Whitfield, Miss Helen Hall, Sir John Tweedy (President of the Fund), and Mr. Hurry Fenwick. At the meeting in the month of May the committee had a balance of only £27 0s 1d, in June a deficit of £16 3s 5d, and in July a balance of £24 13s. Grants in relief were made in May of £197, in June of £190, and in July of £280 15s, £667 15s in all, the amount expended thus exceeding the receipts by no less than £632 5s 4d. The need of liberal and immediate relief is obvious, and subscriptions should be sent to Dr Samuel West, at 11, Chandos street, Cavendish square, W. We refer our readers to a letter from Dr West published in another column.

We deeply regret to learn of the death of Sir Victor Horsley, which occurred in Mesopotamia at the beginning of this week. In him we have lost one of the first exponents of British surgery, a great physiological discoverer, and a forceful and generous personality. His death will be universally deplored.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

MEETING OF COUNCIL

A QUARTERLY meeting of the Council was held on July 13th. Sir W. WATSON CHEYNE, the President, being in the chair.

Sir W. Watson Cheyne was re-elected President of the College and Mr. Harrison Cripps and Mr. Charters Symonds were elected Vice Presidents for the ensuing collegiate year.

The PRESIDENT announced the result of the recent election of members of Council. Mr. Haslam and Mr. Johnson were introduced, and they made declarations in the terms of the oath prescribed by the Charter of 1820 and took their seats in the Council. Mr. Charters Symonds, re-elected on a previous occasion, was also introduced.

It was resolved to grant jointly with the Royal College of Physicians of London Diplomas in Public Health to three successful candidates.

The PRESIDENT reported on behalf of himself and the Vice Presidents that as requested by the Council in July 1915 they had on Dec. 14th 1915 Jan. 8th and July 6th 1916 held conferences with Sir Arthur Downes and Dr. Faller of the Local Government Board on the subject of the special laws for local medical officers and that as a result of these conferences it was proposed to

recommend to the Board to introduce several alterations and amendments in the General Order of the Board relating to the matter

Sir FREDERIC FAR reported his attendance, as the representative of the College, at the meetings of the committee appointed by the Commissioner of Police to consider the conditions under which licences to drive motor-cars might be granted to maimed persons, he stated that the committee had now sent in its report

A letter was read from the Rubber and Tin Exports Committee stating that largely owing to the kind assistance of Mr S G Shattock, the questions which had arisen in connexion with the export from this country to neutrals of surgical rubber goods have now been settled satisfactorily and thanking the College for the assistance given in the matter

A letter was read from the assistant secretary of the Royal Society forwarding a copy of regulations for the organisation of a Conjoint Board of Scientific Societies adopted at a conference of the societies concerned convened by the Royal Society and asking the College to nominate two representatives to the Board in accordance with the provisions of the scheme The President and Sir John Bland Sutton were named

A letter was read from Sir Alfred Pearce Gould resigning his membership of the Committee of Management and of the Executive Committee of the Imperial Cancer Research Fund The best thanks of the Council were given to Sir Alfred Pearce Gould for his services Mr Haslam was appointed a member of the Committee of Management and Mr Bilton Pollard was appointed a substitute member for Sir George Makins Mr D Arcy Power was elected a member of the Executive Committee of the Imperial Cancer Research Fund

The following professors and lecturers were appointed — Hunterian Professors — Dr Arthur Keith Six lectures on the *Anatomy of the Human Body*, Mr Jonathan Hutchinson One lecture on the *Surgical Treatment of Trigeminal Neuralgia*, Mr Robert Henry Elliot Two lectures on the *Operation of Couching of the Lens for Cataract as Practised in India*, Mr William Sampson Handley One lecture on *Paget's Disease of the Nipple*, Mr Alfred Edward Webb Johnson One lecture on the *Surgical Complications of Typhoid and Paratyphoid Fevers*, Mr Frank Cook One lecture on *Gunshot Wounds of Joints, their Pathology and Treatment* Aris and Gale Lecturers — Mr Ernest W Hey Groves One lecture on *Bone Growth and Bone Grafting*, Dr Wilfred Harris Two lectures on the *Morphology of the Brachial Plexus in its Relation to Surgery* Erasmus Wilson Lecturer — Mr Samuel George Shattock Six demonstrations on *Surgical Pathology* Arnott Demonstrator — Dr Arthur Keith Eighteen demonstrations on the *Anatomy of the Human Body* These demonstrations with the six Hunterian lectures, are to form a course of 24 lectures suitable for ambulance and first-aid students, 12 to be given in the autumn of 1916 and 12 in the spring of 1917 Odontological Demonstrator — Mr James Frank Colver Two demonstrations on *Fractures of the Jaw*

The Council resolved that the attention of the Fellows and Members of the College should be called to the improper use which may be made of medical certificates and the responsibility which is attached to their issue, the resolution arising out of the statements made to the College that the Naval authorities had complained of laxity

DONATIONS AND BEQUESTS — The late Miss Ellen Constantia Hodgkinson of Preston Lancs has bequeathed £1000 to the Royal Infirmary at Preston £500 to the Preston Parish Nurses Fund and £300 to the Church of England Zenana Missionary Society — By will the late Mrs Mary Jane Smith of Leamington has bequeathed £200 to the Earlswood Asylum for Idiots and £500 to the Warneford Leamington and South Warwick General Hospital — The late Miss Agnes Crowler, of Warlebone has left property of the value of £12 9 9 to be divided subject to life interests, among the Hospital for Sick Children, Great Ormond Street the Inwood Cottage Hospital Alton, the Governors Benevolent Society, the Surgical Aid Society the Hospital for Women Soho-square the Middlesex Hospital the Alton Town Nursing Home and the National Benevolent Society and the Hazelwood House Branch of the Y M C A Hyde — The Chelsea Hospital for Women has received two anonymous donations of £1000 each to establish memorial beds in the new hospital — Sir John Llewellyn has given the further sum of £1000 to the Swansea Hospital

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

To be temporary Surgeons John A D Skinner R O Townsend, and T R F Kerby

The following appointments have been notified — Lieut Surgeons J St T Murphy to the *Commonwealth* and R St G S Bond to Plymouth Hospital

ARMY MEDICAL SERVICE

Lieutenant-Colonels to be temporary Colonels whilst Assistant Directors of Medical Services R J W Mawhinney and D J Collins

Canadian Army Medical Corps Majors to be temporary Lieutenant Colonels G Bourgeois E A Le Bel F H Le de Martigny, and H J Theriault Captain R Navrand to be temporary Major

SPECIAL RESERVE OF OFFICERS

Royal Army Medical Corps

Temporary Lieutenant D R Jones, from R A M C, to be Captain

Staff Sergeant C O J Young, from Dublin University Officers Training Corps, to be Lieutenant (on probation)

TERRITORIAL FORCE

Royal Army Medical Corps

Welsh Field Ambulance R R Powell to be Lieutenant

Welsh Border Mounted Brigade Field Ambulance C Jephcott, to be Lieutenant

Highland Field Ambulance Lieutenant G Torrance to be Captain

Lowland Field Ambulance Captain L S Forde, Scottish Borderers to be temporary Major

Southern General Hospital Captain L G Parsons is seconded

London Sanitary Company The undermentioned Lieutenants to be Captains J Davidson, H Duguid W S H Campbell, W A I Balfour Browne, and R A Ashkin

West Lancs Casualty Clearing Station Lieutenant F M De Jong to be Captain

West Lancs Divisional Sanitary Section Lieutenant A Reid to be Captain

Attached to Units other than Medical Units — Lieutenants to be Captains F M Hughes and T F Saunt. P Pope to be Surgeon Captain in the Territorial Cadet Training Corps

THE CONSERVATION OF CHILD LIFE — Dr Maxwell Williamson, medical officer of health of Edinburgh has prepared a scheme for the conservation of child life, which is to be considered by the public health committee of the town council Dr Williamson points out that the Notification of Births Act 1915, confers upon local authorities the power to frame and carry out schemes for the preservation of the mother during her maternity periods and for supervision over the lives of the children under 5 years of age He says that in every large community there is a serious sacrifice of child life which could be very materially reduced under special care and the adoption of every possible preventive measure The two principal causes of death in Edinburgh are measles and whooping cough but even more important as causes of death are those resulting from premature birth or associated in some way with maternity conditions which under suitable treatment are undoubtedly preventable In Edinburgh there are already a great many agencies whose special object is the benefit of the child and the mother and Dr Williamson's scheme is to link up all these into one whole The two main centres would be the Royal Hospital for Sick Children and the Royal Maternity Hospital and the different dispensaries in the city would be subsidiary centres At these centres provision would be made for adequate treatment the whole of the supervision being under the medical officer of health The additional office staff necessary would include one lady doctor two female clerks two female official visitors and six district nurses Certain other existing institutions would be included in the scheme and maternity and child clinics would be established The names of expectant mothers entering the former would be duly registered and if the person is so insured as to be unable to pay the fee of a doctor, she would be supplied with and if necessary would cost up to a pound the expenses of the birth of the child The child clinic would be open to the care of infants and children from the time of birth to the age of 5 years. Persons would be kept and supplied with milk etc. supplied free The cost of the scheme would be £612 per annum

Obituary.

ELIE METCHNIKOFF

VICELAUREAT, SUB-DIRECTOR OF THE PASTEUR INSTITUTE IN PARIS

A YEAR ago we recorded the death of Paul Ehrlich and now his great contemporary Elie Metchnikoff has passed away. Twenty years ago their teaching of the mechanism of immunity, the one representing the German 'humoral' school, the other the French 'cellular' school—was still in the sharpest possible contrast. Now in the fuller light of modern bacteriological research, the two views have almost become blended into a harmonious whole.

To Metchnikoff we owe the first serious attempt to explain the resistance of the body to bacterial invasion. Setting aside the crude and speculative views put forward by Pasteur and Chauveau who regarded the animal body as a mere culture medium for the growth of micro-organisms which soon died in it until the necessary pabulum was exhausted or their own products choked them, Metchnikoff formulated the conception of an active bodily defence finding its mechanism in the functions of the leucocytes. Panum (1874) and Rost (1881) had previously suggested that bacteria might be ingested by these cells, but to Metchnikoff is due the entire development of the idea that leucocytes possessed as a normal function the power of digesting and destroying foreign particles, and among them the invading parasitic organisms. It was in 1883, in an address delivered at Orléans before the Congress of Naturalists and Medical Men, that he first propounded the doctrine of phagocytosis as the main defensive agency of the body.

He backed this by upbringing a biologist, and his views were naturally founded upon a long series of patient studies on the lower forms of life, enabling him to trace the phagocytic process from the lowest up to the most complex members of the animal kingdom. The central fact of his theory could readily be verified by anyone, and throughout phagocytosis he immediately gained a wide recognition. At the time the properties of the microbe were very imperfectly understood, and the influence of the body on the life of the body had not entered into account. During the 15 years which followed his work on the phagocytosis of leucocytes gradually became known, and the importance of that mechanism was fully

noted by Fodor (1887) and expounded by Buchner (1889) in his alexane theory in fundamental antagonism to Metchnikoff's views. Pfeiffer's enunciation of the doctrine of bacteriolysis in 1894 paved the way for Ehrlich's comprehensive study of humoral phenomena, and for a very wide acceptance of the side-chain theory which ascribed the dominating influence in the body's defence to the fluid elements of the blood. Ehrlich was a chemist and his theory naturally followed on his investigations of the specific action of dyes on living tissues.

It is a matter of recent history how these two apparently widely divergent views can be harmonised. Undoubtedly the most important step in this direction was taken by Wright when he popularised the notion of the necessity of the presence of a humoral element in the blood preparing

the bacteria for phagocytosis. Denys and Leclef in 1895 had partly foreshadowed this result, but the teaching of the Louvain school had not attracted any wide attention. It is enough to point out here how the opsonin theory of Wright, the bacterotropin theory of Neufeld and the agglutinin theory of Bail have gradually reconciled the views of Metchnikoff and Ehrlich in a harmonious theory of the resisting powers of the whole blood as a complete tissue, on which the symmetrical modern structure of immunity is being firmly built up.

Of Metchnikoff's writings the most important is the 'Immunity in Infectious Diseases' (1901), summing up as he himself states the labours of 25 years. This book he dedicated to MM. Duclaux and Roux, generously acknowledging their assistance to a zoologist who had wandered into the domain of biological chemistry and medical science. Of this work an English translation appeared in 1905 (Cambridge University Press).

In another large book, 'The Nature of Man: Studies in Optimum Philosophy' (English translation 1903, W. Heinemann), Metchnikoff enunciated his creed that the fear of death, which grows as old age creeps upon us, is only the prompting of an instinct which tells us that we are dying before life's span has run its natural course. He claimed that senile decay was mainly due to the destruction of the higher elements of the organism by macrophages, saying that 'if intestinal and other toxins were eliminated by modern surgical methods, and appropriate hygiene the number of man's days might be greatly extended until he should meet a natural death whose coming would be welcome. Later on, as is well known, Metchnikoff found in the Belgian bacillus an agent to assist the production of longevity. The Harben lectures on the 'New Hygiene' delivered in French in May 1906 and reprinted

ELIE METCHNIKOFF

SUB-DIRECTOR OF THE PASTEUR INSTITUTE, PARIS

in a small volume (1906 W. Henemann), dealt in a popular manner with the subjects of his larger works, and in the third lecture with the inunction of mercurial ointment as a prophylactic against syphilitic infection, based on the successful protection of apes by this method.

Elie Metchnikoff was born at Kharkov, in Russia, in 1845, and died at the Pasteur Institute in Paris, on July 15th, 1916, at the age of 71 years. After graduating at Kharkov University at the age of 19, he studied at Giessen, Göttingen, and Naples, becoming professor of zoology in the University of Odessa when he was 25. Five years after publication of his thesis on phagocytosis, in 1888, he received an invitation from Pasteur to work with him in Paris at the laboratory in the École Normale, which was the predecessor of the Pasteur Institute, at which he was later appointed sub-director. He remained in Paris, where his death has now occurred nearly 30 years later. Metchnikoff was a foreign member and medallist of the Royal Society, a foreign member of the Linnean Society, an honorary member of the Manchester Literary and Philosophical Society, an honorary D.Sc. of Cambridge and a member of the Academy of Sciences of Paris and Petrograd. In 1908 he was awarded a Nobel medal, and only a few weeks ago the Albert Medal of the Royal Society of Arts was conferred upon him in recognition of the value of his investigations into the causes of immunity.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

In the 96 largest English and Welsh towns with populations exceeding 50,000 persons at the last Census, 7852 births and 3552 deaths were registered during the week ended Saturday, July 15th. The annual rate of mortality in these towns which had been 12.6, 11.6, and 11.1 per 1000 in the three preceding weeks, fell in the week under notice to 10.7 per 1000 of their aggregate civil population estimated at 17,312,295 persons for the year 1915. During the 13 weeks of last quarter the mean annual death rate in these towns averaged 14.3, against 13.8 per 1000 in London. Among the several towns the death rate last week ranged from 4.2 in Ipswich, 4.7 in Ealing, 4.8 in Southend-on-Sea, 4.9 in Blackpool and 5.0 in Leyton and in Barrow in Furness to 14.5 in Wigan, 14.8 in Stockport, 15.3 in Walsall, 15.6 in Carlisle and 21.0 in Hastings.

The 3552 deaths from all causes were 141 below the number in the previous week, and included 222 which were referred to the principal epidemic diseases against numbers declining from 335 to 224 in the six preceding weeks. Of these 222 deaths, 62 resulted from measles, 51 from infantile diarrhoeal diseases, 47 from diphtheria, 40 from whooping-cough, 15 from scarlet fever, and 7 from enteric fever but not one from small pox. The annual death rate from these diseases was equal to 0.7 per 1000 and coincided with that recorded in each of the four preceding weeks. The deaths attributed to measles which had been 67, 63, and 60 in the three preceding weeks, slightly rose to 62 and included 18 in London, 7 in Liverpool, 4 in Sheffield and 3 each in West Ham, Walthamstow, and Newcastle-on-Tyne. The deaths of infants (under 2 years) from diarrhoea and enteritis which had been 45, 50 and 54 in the three preceding weeks, fell to 51 of which 16 occurred in London, 4 in Liverpool and 3 in Birmingham. The fatal cases of diphtheria, which had been 27, 29 and 35 in the three preceding weeks further rose to 47, and included 13 in London and 3 in Liverpool. The deaths attributed to whooping-cough, which had been 77, 55 and 61 in the three preceding weeks fell to 40, 8 deaths were recorded in London, 5 in Birmingham, 4 in Liverpool, and 3 in Manchester. The deaths referred to scarlet fever which had been 15, 13 and 4 in the three preceding weeks rose to 15 and included 4 each in London and Liverpool and 2 in Southampton. The fatal cases of enteric fever, which had been 13, 10, and 9 in the three preceding weeks further fell to 7 but showed no excess in any particular town.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital which had been 1303, 1273 and 1262 at the end of the three preceding weeks further declined to 1236 on Saturday last. 150 new cases were admitted during the week against 171, 162, and 170 in the three preceding weeks. These hospitals also contained on Saturday last 127 cases of diphtheria, 195 of measles, 162 of whooping-cough and 147 of enteric fever but not one of small pox. The 859 deaths from all causes in London were 4 in excess of the number in the previous week, and corresponded to an annual death rate of 10.8 per 1000. The deaths referred to diseases of the respiratory system which had been 157, 107 and 90 in the three preceding weeks rose to 117 in the week under notice.

Of the 3552 deaths from all causes in the 96 towns, 1 resulted from violence and 263 were the subject of coroners' inquests, while 1152 occurred in public institutions. The causes of 34, or 1.0 per cent of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Sheffield, Leeds, Bristol, Bradford, Newcastle-on-Tyne, and in 65 other smaller towns. Of the 34 uncertified causes, 7 were registered in Birmingham and 2 each in London, Liverpool, and South Shields.

HEALTH OF SCOTCH TOWNS

In the 16 largest Scotch towns with an aggregate population estimated at 2,372,000 persons at the middle of this year 1093 births and 571 deaths were registered during the week ended Saturday, July 15th. The annual rate of mortality in these towns, which had been 13.4, 12.6 and 12.4 per 1000 in the three preceding weeks, rose to 12.6 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death rate in these towns averaged 15.3 or 1.0 per 1000 in excess of that recorded in the large English towns. Among the several towns the death rate last week ranged from 2.9 in Perth, 7.8 in Avon and 8.0 in Hamilton and Clydebank, to 14.0 in Kilmarnock, 16.0 in Coatbridge and 18.4 in Falkirk.

The 571 deaths from all causes were 8 in excess of the number in the previous week, and included 44 which were referred to the principal epidemic diseases against 54 and 46 in the two preceding weeks. Of these 44 deaths, 18 resulted from measles, 8 each from whooping-cough and infantile diarrhoeal diseases, 7 from scarlet fever, and 3 from diphtheria, but not one from enteric fever or from small pox. The annual death rate from these diseases was equal to 1.0 against 0.7 per 1000 in the large English towns. The deaths attributed to measles, which had been 19, 23, and 19 in the three preceding weeks numbered 18 of which 13 occurred in Glasgow and 3 in Leith. The deaths referred to whooping-cough, which had been 4, 5 and 8 in the three preceding weeks were again 8 last week, and comprised 5 in Glasgow and 3 in Coatbridge. The fatal cases of diarrhoea and enteritis (among infants under 2 years), which had been 11, 13 and 5 in the three preceding weeks rose to 8, and included 4 in Glasgow. The deaths attributed to scarlet fever, which had been 7, 1, and 8 in the three preceding weeks numbered 7 last week, of which 5 were registered in Glasgow. The 3 deaths from diphtheria were 3 below the average in the 13 weeks of last quarter, and comprised 2 in Glasgow and 1 in Kirkcaldy. In addition to the above deaths 3 fatal cases of typhus were registered in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 75, 57 and 64 in the three preceding weeks fell to 50 in the week under notice and were 10 below the number registered in the corresponding week of last year. The deaths from violence numbered 16, against 22 and 23 in the two preceding weeks.

HEALTH OF IRISH TOWNS

In the registration area of Dublin 182 births and 143 deaths were registered during the week ended Saturday, July 15th. The annual rate of mortality which had been 15.9, 17.3 and 17.6 per 1000 in the three preceding weeks was 18.3 in the week under notice or excluding 27 deaths resulting from the recent disturbances it was equal to 15.3 against 10.8 and 13.7 per 1000 in London and Glasgow respectively.

Of the 143 deaths at all ages, 17 related to infants under 1 year and 29 to persons aged 65 years and upwards. Two deaths were referred to whooping-cough and 1 each to measles, scarlet fever, and infantile diarrhoea.

The causes of 33 deaths were uncertified, an 12 others were the subject of coroners' inquests while 52 or 35 per cent of the total deaths occurred in public institutions.

During the same period 165 births and 110 deaths were registered in the city of Belfast. The deaths corresponded to an annual rate of 14.7 or 2.3 per 1000 higher than that recorded in the previous week, and included 15 of infants under 1 year and 19 of persons aged 65 years and upwards. Four deaths were referred to measles, 2 to scarlet fever, and 1 each to enteric fever, whooping-cough, and infantile diarrhoea. The causes of 2 deaths were uncertified and 7 others were the subject of coroners' inquests while 31 occurred in public institutions.

TRAFFIC IN NARCOTIC DRUGS.—The conviction of F. J. M. Marlowe, alias "the doctor," of the County of London, charged with being concerned in the sale of opium, a member of His Majesty's Forces, has called attention to a case of affairs which has long given rise to anxiety in medical circles. An action was taken under a recent Army Order based upon the Defence of the Realm Act, 1914, to the effect that in the event of the Government being satisfied that a person has been or is likely to be concerned in the preparation, distribution, or sale of any narcotic drug, the person may be arrested and detained for a period of 28 days.

THE NATURE OF THE CHANGES WHICH OCCUR IN MUSCLE AFTER NERVE SECTION

To the Editor of THE LANCET

SIR,—There are one or two points in Dr h Hernaman Johnson's letter in your issue of July 15th on which I may perhaps be allowed to make a few remarks

1 Dr Herniman Johnson says that it is easy to believe that sufficiently violent faradism will cause contraction in denervated muscles. This mode of expression seems to imply what is more definitely stated in the late Dr Lewis Jones' work on Medical Electricity —viz, that after nerve section there is a rapid early fall in the irritability of the muscle fibres. I do not think this is the case. The fall of irritability seems to me to be gradual throughout. When a rapid decrease of irritability is observed it is, I think, due to nerve degeneration. Strong faradic currents are required to stimulate directly muscle fibres whether they are normal or denervated when large electrodes are used and they are placed on the skin overlying the muscles, but weak currents are sufficient if the electrodes are small and they are placed directly on the muscle. I have thus obtained contraction in denervated muscles (which had lost about 50 per cent of their weight) on stimulating them with faradic currents which I could barely feel on the tip of the tongue.

2 On general grounds I should be inclined to agree with Dr. Hermann-Johnson that electrical stimulation causing contraction is beneficial in the stage of regeneration but the earlier the stage the greater care should I think be taken to avoid fatigue since regenerating nerve is very easily fatigued by electrical stimulation and the normal impulses thus cut off. Whilst I do not think that contraction caused by electrical currents has any appreciable effect in preventing the wasting of denervated muscle I have not found that it causes any appreciable increase of wasting. Its harmful effect when it has any probably occurs in cases in which it produces traction of the nerves and in consequence delays regeneration.

3 Dr Hermann Johnson urges physiologists to abandon the use of the faradic coil. He is I think under some misapprehension as to the use to which the faradic coil is put in physiological laboratories. Its merits and demerits have received a great deal of attention, and have been fairly thoroughly worked out. For purposes of accurate measurement of nerve or muscle irritability the coil with vibrating hammer is so used. The methods which are used may be gathered from papers published in the *Journal of Physiology* during the last 10 years by Dr Keith Lucas by the late Prof^r de Mire and by Mr Adrian (Condenser currents I may mention were employed by Professor Waller in 1899). But for a first approximation a du Bois Reymond coil or some modification of it gives sufficiently accurate results and it would be a sensible to dispense with its use as it would be to give up the ordinary thermometer because we can read to a variation of temperature to about a millionth of a degree centigrade.

I am & r yours faithfully

THE RELIEF OF DISTRESS IN THE
MEDICAL PROFESSION ARISING
OUT OF THE WAR

THE LANCET

1. The National Relief Council much desires in the
of relief and it is certain to free off the war
of relief. The distress will gradually relieve
the war is over a little distress now arising
from the cold. The National Relief Council distress
from the war. The American Relief Council which has
been set up all over the world on the line of the railway
to the relief of the people of the world.

in the war and who are subscribers to that Fund. This requires a large capital sum and involves considerable liabilities extending over many years. Worthy as such an object is in itself, it does not deal with the immediate distress at all.

A scheme which appears to be strongly supported proposes to deal with this temporary distress by way of loans. For such a purpose a very large sum will be necessary. It is a scheme which no doubt would be very appropriate for certain cases, but experience has shown that a loan fund is very difficult to administer satisfactorily. Loans too, require time for arrangement, and in many of the most urgent cases time is pressing and there may be no security upon which loans can be safely raised. In most cases what is required is immediate help and often to a substantial amount. It is this class with which the Royal Medical Benevolent Fund is already dealing, so far as its means permit from its Emergency Fund, for which a special appeal was issued last week. This department of the Fund is a going concern and it only needs larger resources. I have not seen that it has been proposed to form any new fund upon the same lines, and on general grounds such duplication is neither necessary nor desirable. The profession wants I am told a workable scheme, and I make this suggestion in the belief that this plan would be the simplest and least expensive way of dealing with the problems that have arisen.—I am, Sir, yours faithfully,

Wimpole-street W July 18th 1916

SAMUEL WEST

THE ODOUR OF PAINT AS A CAUSE OF PLUMBISM

To the Editor of THE LANCET

Sir — In your annotation of May 27th, in which my article in the same issue on the Odour of Paint as a Cause of Lead Poisoning is referred to the question of cooking utensils as the source of the lead was put forward I had previously inquired into this but on being told that only iron saucepans were used I went no further into the matter, not realising that this domestic article was 'tinned' On later investigation I found that of two iron saucepans in use (the ordinary tinned variety) one was to all appearances sound and gave no ocular evidence of lead, the other, smaller and more frequently used had at the bottom half its area covered with what looked very like solder cutting and glistening like this alloy Its presence was explained by the saucepan having "caught" at some time I filled it with rain water and to make sure of this being strongly alkaline added some soda which is sometimes done in the cooking of vegetables The water was then boiled for three hours and a sample was sent to the Clinical Research Association who reported that the specimen was examined for lead with entirely negative results With regard to other cooking articles the frying pan in use is blameless and no enamelled ware is used Against the saucepan being the source of the poisoning is the negative report and the fact that although in continuous use the patients are now well I am informed by a woman that tinning consists in running on to the inside of the pot a mixture of lead and tin I believe in equal proportions It therefore puzzles me that lead does not get into the system more frequently than it does because it must surely take some time for a protective covering to form and render the alloy innocuous — I am Sir yours faithfully

MARY MURDOCH MEMORIAL LOAN FUND

To the Editor of THE LANCET

Sin - This fund has been raised to perpetuate the memory of Dr. Mary McDoch her high professional standard and the inspiration and encouragement she was to her colleagues and friends. By its means it is hoped that the remembrance of her work for women will not pass away with the generation of those who have known and loved her.

The committee which has been formed to administer this fund is prepared to grant loans of £100 or less free of interest to give women doctors some financial help at a time when they may specially need it. Such special need might be during their early years of establishment.

practice, to enable them to study some special subject or purchase some particular apparatus, &c., thus making their work more valuable and efficient.

This fund will be open to all medical women but special preference will be given to those who have been trained at the London School of Medicine for Women, which was Dr Murdoch's own school.

All applications will be regarded as confidential, and should be made to the Hon Mrs Franklin, 50, Porchester terrace, London W.

I am, Sir, yours faithfully

H FRANKLIN,

Hon Secretary and Treasurer to the Mary Murdoch Memorial Loan Fund

July 17th, 1916

MEDICAL WOMEN'S FEDERATION

To the Editor of THE LANCET

SIR,—Owing to an oversight in proof correcting on my part there is an error in your sympathetic paragraph on the formation of the Medical Women's Federation. The word "President" following the signature of Dr Helen Boyle should have been deleted. It refers to one only of the federated associations—viz, the Registered Medical Women's Association. None of the officers of the Federation have been appointed.—I am, Sir, yours faithfully,

JANE WALKER,

Secretary and Treasurer (pro tem)

Harley street W July 17th, 1916

THE TREATMENT OF OSTEO-ARTHRITIS BY CONTINUOUS COUNTER IRRITATION

To the Editor of THE LANCET

SIR,—I have read with much interest Mr Wheeler's paper on operative treatment of osteo-arthritis in THE LANCET of June 24th.

It is a matter of extreme regret to me that so few writers allude to the method of continuous counter irritation, as recommended by Dr P W Latham when dealing with arthritis. He writes "Upon the foregoing data it is not unreasonable to assume that the joint troubles in rheumatoid arthritis are due to spinal congestion or chronic myelitis chiefly affecting the ganglion cells of the anterior horns, but extending also, when the disease is associated with glossy skin, to the ganglion cells in the posterior horns. If this is the case, the natural inference would be that, in the earlier stages of the malady at all events, the treatment should be directed to the abatement of this spinal congestion, and that probably this can be most effectively done by cupping or blistering the spine." I have personally practised this for over 18 years in all classes of cases of arthritis whether rheumatoid, osteo-arthritis, or septic, and am convinced it is a most valuable means of arresting the disease process. In fact I never think of advising surgical procedures of any kind until my patients have been carefully treated by this means and I am convinced the disease is for all practical purposes quiescent. In the decided majority of cases I am of opinion it is superior to vaccines or any other form of treatment.

A vivid light has been thrown on how such measures act by Dr Gougerot, of Paris who states "that a mechanism exists by which germs and toxins are conveyed from various parts of the system to the skin, by the blood where they are fixed and burnt up. Also that this mechanism may be heightened by artificial stimulation of the skin by means of irritants." I am, Sir, yours faithfully

OBLITERATIVE ARTERITIS AND LEAD POISONING

To the Editor of THE LANCET

SIR—In the issue of THE LANCET of June 3rd 1916 on p 1133 you publish in an annotation on the above subject an abstract of a case of arteritis obliterans due to lead poisoning reported by me. The case was published in the

1 The Pathology and Treatment of Rheumatoid Arthritis. THE LANCET April 6th 1913 p 24.

2 Medical Press and Circular June 7th 1913

Conferences of the Neurological Institute of New York, and it might be of interest to your readers to give them its outcome.

The man was operated upon by Dr Dowd in New York in the early part of this year. The left foot was amputated a few inches above the ankle. During the operation the tourniquet which had at first been applied was removed and there was no bleeding from the cut surfaces or from the bony canal. It was much as though one were operating upon a cadaver. In spite of this apparent lack of circulation the man made a good operative recovery. The muscular tissue that was removed at the operation was examined and found to contain large amounts of lead, and the cross section of one of the arteries showed an obliterating arteritis with hypertrophy of the middle coat of the artery together with the disappearance of portion of the intima, giving an appearance similar to that described by Kolisko.

I am, Sir, yours faithfully,

New York City June 25th 1916.

WAITER TIMME, M D

TUBERCULOSIS AND SQUINT

To the Editor of THE LANCET

SIR,—I have found squint to be much commoner in tuberculosis both pulmonary and extra pulmonary, than in healthy members of the general population similar in respect of age, sex, and social condition. seemingly squint is a sign of tuberculous predisposition. The figures are in 5000 patients positive consumptives 6 cases of squint, in 100 surgical tuberculous patients, 2 cases, and in 1050 non tuberculous persons, 3 cases.

The only previous observation of this kind found is by no less an author than Homer. It is interesting to think that the picture of Thersites—

'Cross-eyed he was and halting moved on legs
Ill paid his gibbous shoulders o'er his breast
Contracted pinch'd it ..

was drawn from a tuberculous cripple of soured disposition and of that anti authoritarian bent which was less in favour then than now.

I am, Sir, yours faithfully,

July 13th 1916.

W O RIVERS

FAT-HEADEDNESS

To the Editor of THE LANCET

SIR,—Your correspondent of July 15th, who screens him self under the guise of "Hospital Superintendent" makes the offensive assumption that I went to the committee. I did not. The hospital was represented by another official. From the tone of his letter I infer that "Hospital Superintendent" is eminently suited to be a member of the committee.

I am, Sir, yours faithfully,

R G HERN

The Laboratory Westminster Hospital, July 17th 1916

THE QUESTION OF PRIVATE OPERATIONS ON SOLDIERS

To the Editor of THE LANCET

SIR,—The following case may interest your readers. This week a private (of independent means) in the Australian Forces was sent to me in consultation by a general practitioner as to the expediency of a certain operation. This I agreed was necessary. The patient wished it performed soon and expressed a special wish that I should perform it. I gave him at his request a fully explanatory certificate. With this he asked for leave. His superiors refuse him permission for a private operation giving as their reason that the Australian authorities are responsible for him and therefore if he has an operation it must be done by an Australian surgeon in an Australian hospital.

This appears to me to be a very high handed way of dealing with a patriotic volunteer and incidentally a very poor compliment to British surgery.

I am, Sir, yours faithfully

THE CENTRAL MEDICAL WAR COMMITTEE

Meetings of the Committee were held on Wednesday, July 19th, and the following day to consider appeals for exemption from military service

It was agreed to remit to the Executive Committee a suggestion that a list of the medical men who have gone on active service during the previous week should be sent to the medical journals for publication, the list being classified according to areas

The Committee of Reference of the English Royal Colleges

The work of the Committee of Reference of the English Royal Colleges in assisting the Central Medical War Committee has been of great value, a difficult and delicate part of the labours of the central body has been much facilitated thereby. The constitution of the Committee of Reference it will be remembered is as follows. Dr Frederick Taylor Sir Rickman Godlee Dr W Pasteur Dr Sidney Martin Dr H G Turner Mr W F Haslam Mr D Arce Power and Mr Charles Ryall with Mr Hallett as honorary secretary. The function of the Committee is to advise the Central Medical War Committee as to exemptions of medical men attached to the hospitals in the London County Council area either as members of the honorary staffs or as teachers or as residents who may be called up for service. The Committee of Reference has been able to keep in touch with the Central Medical Committee by means of a joint committee composed of Dr Pasteur Dr Sidney Martin Mr Ryall and Mr Hallett (secretary) representing the Committee of Reference

and Dr C Battar, Mr T Jenner Verrall Mr F B Terz and Dr Alfred Cox and Mr Bishop Harman (secretaries), representing the Central Medical War Committee. By its deliberations of this jointly constituted body the Central Medical War Committee is placed in a position to acquire much preliminary information with regard to the suitability for commissions in the Royal Army Medical Corps of medical men attached to the staffs of hospitals and medical schools. The questions on which the Committee of Reference have been and will be, able to guide the Central Medical War Committee are many of them of considerable complexity. For example, there is no known standard for the constitution of a general or special hospital, in accordance with which it can be stated that a staff of a certain number assisted by residents of a certain number is required for a certain number of beds. To some extent it may be said that no such pattern can exist inasmuch as special hospitals have special requirements and general hospitals vary largely in themselves—distance from the residential centre of the staff or association with a medical school, being, for example, two things which may entail an apparently large personnel. The Committee of Reference will make allowance for such things in dealing with the situation on general lines if the information is freely given to them by the institutions concerned. This, we are certain, will generally occur but it is a fact that the attitude of all hospitals in asking for exemption of their staffs has not been precisely similar, far more requests for exemption having come from some institutions than from others. Endeavours to treat such matters fairly will probably lead to some of the exemptions granted being granted only for short spaces of time. In this way opportunity will be afforded to consider the plight of institutions which assert themselves to have been unduly depleted

SCOTTISH MEDICAL SERVICE EMERGENCY COMMITTEE

At the monthly meeting of the Committee held in the Royal College of Physicians Edinburgh on July 15th the convenor reported that it was expected that the July contingent joining the R A M O would be about 100. The Register had been carefully gone over and of the medical men in Scotland who having qualified in 1895 or subsequently, were possibly under the age of 41 only 69 had failed to register their names as willing to accept a commission if called upon to do so. Their names had been transmitted to the military authorities

THE ROYAL ARMY MEDICAL CORPS AND THE GREAT ADVANCE

Early in the course of the fighting, in what will presumably come to be called the battle of the Somme, the Commander in Chief, Sir Douglas Haig issued a Special Order of the Day possessing the greatest significance to all our readers. The Order was read on parade to all medical units by instructions from the Deputy Directors of Medical Services, to whom it was addressed in these words—

The Commander in Chief directs me to convey to you and through you to the directors and all concerned under them his high appreciation of their hard work and the efficiency of arrangements for dealing with the medical aspect of the present situation

This commendation from Sir Douglas Haig will be a legitimate source of gratification to all the medical profession. A preponderant part of the work of the Royal Army Medical Corps is necessarily being done by temporary or Territorial officers serving under and with the Permanent officers so that the corps in its present state is as good as any part of our great Expeditionary Force. How big the organization and personnel of the corps must have been tried during the early days of the great advance of the Allied Forces on the Western front can be measured to some extent by the casualty lists and the fact that the number of wounded who will be in a brief space of time a number of their fighting comrades is so very large. It is a practical commentary upon Sir Douglas Haig's Order proving that the details of collection transport and arrangement of the wounded proceeded swiftly and efficiently despite the conditions produced by the tremendous struggle. It is all the more the case of the highest value in war-time life

OBITUARY OF THE WAR

WALTER SEYMOUR ARMSTRONG M.R.C.S. ENG.,
CAPTAIN ROYAL ARMY MEDICAL CORPS

Captain W. S. Armstrong who was killed in France on May 31st at the age of 42 years was the youngest son of the late Rev. William Armstrong, incumbent of St. Marks, Dalston, and of Mrs. Armstrong of Twyford Lodge Patney. He was educated at St. George's Hospital taking the

Conjoint Board qualification in 1903, after which he acted as assistant medical registrar at his own hospital. He subsequently went to Labrador and Newfoundland where he was surgeon of St. Anthony's Hospital and surgeon in charge of the Indian Harbour Hospital and a magistrate. A fellow practitioner in Labrador now at a casualty clearing station in France writes of him 'Armstrong's keenness his devotion to duty, and his thoughtfulness for the people, had greatly endeared him to all

His loss will be greatly felt in Labrador.' Another medical friend writes of him 'Whilst his love for his profession was the dominating factor, he made himself universally popular in all circles and his death has removed from the profession one who devoted his health and strength in its service.' Towards the end of 1914 he applied for a commission in the R.A.M.C. and served first with the British Expeditionary Force in France in 1914-15 and then with the Mediterranean Force returning to France in April last where he remained until his death.

Captain Armstrong was a man of wide experience who had travelled much and who had a large circle of acquaintances. He married in 1905 Florence daughter of the late Mr. Ralph Tannemcliffe of Leigh Lancashire who survives him.

KENNETH HARRISON ALLOA KELLIE M.A. M.B.
B.C. CAMB. M.R.C.P. LOND.

CAPTAIN ROYAL ARMY MEDICAL CORPS

Captain K. H. A. Kellie who was killed in action on June 25th aged 41 was the youngest son of the late George Kellie of Sutherland Avenue W. and Shanklin Isle of Wight and brother of Lawrence Kellie the composer. He was educated at Westminster School, Caius College

Cambridge and St. George's Hospital also studying in Paris, New York and Boston. He qualified as M.R.C.S. and F.R.C.P. Lond. in 1903, M.B. Camb. in 1905 and M.R.C.P. Lond. in 1905. After holding the post of clinical assistant for outpatients at Fiddington Green Children's Hospital, assistant house physician at St. George's Hospital and house physician at the Victoria Hospital for Children he was appointed in 1909 assistant physician at the latter hospital. In 1912

St. Pancras borough council and chairman of its public health committee and a prominent member of the West St. Pancras Conservative and Unionist Association.

At the beginning of the war he served as a special constable, but in April last year he gave up his work in London and took a temporary commission as lieutenant in the R.A.M.C., and was promoted captain on completing a year's service. Originally Captain Kellie was attached to the Guards Brigade but on his return to the front last April he was transferred to the Canadian Contingent as second senior medical officer. He was a well known oarsman, and stroked the London Rowing Club boat at Henley and other regattas. Captain Kellie was a sound, practical physician who devoted much time and patience to his work. He was an excellent colleague in every way—amiable, cheerful and always willing to help to the best of his ability. He will be very greatly missed by his friends, his colleagues, and his patients.

GEORGE HARRY MELVILLE DUNLOP, M.D.,
F.R.O.P. EDIN.

MAJOR, ROYAL ARMY MEDICAL CORPS

Major G. H. M. Dunlop who died at a Red Cross hospital in France on July 3rd, at the age of 57 years was the son of the late James Usher Dunlop. He was educated at the Edinburgh Collegiate School and Edinburgh University, graduating in 1880.

His first appointment was as house surgeon to Leith Hospital, and he afterwards held a similar appointment at the Sick Children's Hospital, Edinburgh, and was later clinical assistant in the skin and gynaecological wards of Edinburgh Royal Infirmary. Major Dunlop was physician to the Royal Blind Asylum, senior physician to the Royal Hospital for Sick Children, an appointment which carried with it a lectureship on diseases of children in the University, and was also examiner in medicine and in diseases of children at the Royal College of Physicians of Edinburgh to the Council of which he was elected when comparatively young. About a year ago he left for France as a major in the Royal Army Medical Corps in company with Professor Alexis Thomson, of Edinburgh University, to take charge of the medical side of a general hospital. He did important work in different places in France until his untimely death as a result of pneumonia after a short illness.

Major Dunlop had made numerous contributions to medical literature the most important being a report on 500 cases of pneumonia in children. He was a good teacher, his clinical lectures were excellent in substance and made attractive to students by lucid exposition and the lecturer's practical knowledge of his subject. Major Dunlop took an active part in medical affairs in Edinburgh combining with strong personal likes and dislikes a broadminded view of the subjects he discussed. He is spoken of by his colleagues as a good friend, a pleasant companion and a trusted physician who will be greatly missed by both patients and friends. He leaves a widow and a son and daughter.

LORD KITCHEN MEMORIAL FUND—No more fitting way of commemorating Lord Kitchen's name could have been devised than the creation of a fund on behalf of officers and men of the Royal Navy and Army who have been disabled or rendered inefficient by the war. The scheme for which the Lord Mayor of London seeks support is to be perpetual and permanent and will be a source to which the names of a great many brave men are owed and for whom help can be sent to the Lord Mayor the Man on

THE PRACTICES OF ABSENTEE MEDICAL OFFICERS

We outlined briefly a fortnight ago the circumstances which have to be taken into account in any scheme designed to conserve for their owners the private practices of members of the medical profession who have accepted or are accepting commissions in the Royal Army Medical Corps. The subject is one which has been always in the mind of both the Central Medical War Committee and the British Medical Association, and a fortnight ago a scheme was laid before the former body for the institution of Local Committees to whom there should be submitted any agreement under which an absentee medical practitioner could contract with the deputy for carrying on his work to the advantage of all concerned practitioners and public. We pointed out that no one scheme could exactly fit all kinds of practice, every medical man's practice being to some extent an individual affair requiring individual treatment if its preservation and cultivation were to be of the best.

The Central Medical War Committee had several schemes under close consideration, each of which was likely to meet with acceptance in some areas, but not to meet the approval of practitioners in others. It now draws attention to the following general principles which it considers to be of great importance—

- (a) No scheme will be satisfactory which has not behind it (i) the goodwill of the men who are to work it; (ii) the confidence of the men who are going on active service; (iii) the strong moral support of the L.M.W.C. This presupposes that the scheme has been fully discussed at a meeting of the whole local profession.
- (b) It is preferable that there should be a legal agreement between the absentee and his deputy or deputies though it is recognised that this may be impracticable in some cases.
- (c) The L.M.W.C. should in such an agreement be vested with the power of dealing with any disputes that may arise between the absentee and his deputies; the decision of the Committee to be binding; the Committee should also have the power of appointing another deputy in case of need.
- (d) Any such agreement should contain a provision whereby the absentee is indemnified against all acts of negligence committed by the deputy.
- (e) The scheme and agreement should in all cases bind the deputies to refuse to act as the medical attendant of the patients they have attended for the absentees until a specified time (one or two years) after the absentees return.

In September, 1915, the Central Medical War Committee issued a circular (W 3) dealing with this subject. It was indicated that the men going on active service had a right to expect that their interests would be protected by those who remained at home, and it was suggested that where a locum tenens could not be provided the work should be done by a division of the money earned by the practice of the absentee on the following lines: (a) Town practices—an equal division of the proceeds between the absentee and his deputy or deputies; (b) combined town and country practices—probably three-eighths to the absentee and five eighths to the deputy, the latter paying the expenses; (c) country practices where travelling expenses are important—a quarter to absentee three quarters to the deputy.

The first agreement of a legally binding nature brought to the notice of the Central Medical War Committee was drawn up in Holland (Lincs.) area and embodies the suggestions made in Circular W 3, with the addition of a clause to protect the interests of a practitioner who dies on service. The clause runs as follows—

In the event of the death of a practitioner on service his practice shall be carried on for one year after that date or until his representatives give notice to one or more of the practitioners at home that they have disposed of his practice whichever shall first happen and in the meantime the representatives of the deceased practitioner shall be entitled to receive and shall be paid the same remuneration as the deceased practitioner would have been entitled to if he had during such time continued to be a practitioner on service.

The following is a detailed scheme which has received a certain amount of support and which is published by the Central Medical War Committee for comment. It is a scheme formulated by Dr T. Campbell of Wigan and has met with a good deal of support in Lancashire. It embodies a novel method of arriving at an equitable remuneration although the result is roughly the same as the equal division of proceeds between absentee and deputy in a town area suggested in circular W 3. The scheme regards as essential that the absentee shall in all cases appoint a deputy or deputies who shall be responsible for the whole of the practice. There are points in this scheme that may commend themselves particularly to Local Medical War Committees in industrial areas.

Scheme for the Care of the Practices of Medical Men on War Service

- 1 Any medical man deciding to take up a commission or being called up for ordinary military service (hereinafter referred to as an absentee) to at once give notice to the Committee referred to in paragraph 18 hereof and such notice shall signify whether the absentee has made arrangements with a medical practitioner or practitioners (hereinafter called the deputy) to carry on his practice in his absence. If arrangements have been so made the name or names and addresses of such practitioner or practitioners.
- 2 If at the date of the said notice the absentee has not made arrangements with a deputy he should as soon as he has done forward to the same Committee the name and address of the deputy.
- 3 If the absentee fails to appoint a deputy then the said Committee on the request of the absentee or of his wife or other authorised representative can make an appointment. The authorised representative of the absentee shall be given power of attorney to act on his behalf.
- 4 The remuneration of the deputy to be agreed as by the absentee but in case no arrangement as to remuneration is made or in case of an appointment by the said Committee the remuneration to be on the following scale—namely £1 1s per week for every £100 gross receipts of the practice during the 12 months ending Dec 31st immediately preceding the deputy's appointment, with a maximum weekly remuneration of £12 12s and a minimum of £3 3s. The said remuneration to be readjusted every six calendar months in accordance with the scale fixed by this paragraph on the gross receipts for the 12 months preceding the date of readjustment. Any fees payable by the Army authorities for an absentee for any appointment held by him shall not be included in the gross receipts of the practice during the preceding 12 months unless the work of such appointment be taken over and carried out by the deputy.
- 5 The deputy to defray out of his remuneration all the work, costs and expenses of the absentee's practice except the rent rates and taxes of the absentee's main and branch surgeries.
- 6 The deputy to keep each day a strict account of his visits, consultations, dressings, operations and medicines with the names and addresses of the patients on whom attendance is made by entry in a same up in absentees day book differentiating between private patients and panel patients (if necessary) and to leave such day book open to inspection of the absentee's wife or other representative who must enter same into ledger at least once a week.
- 7 The record cards of panel patients to be accurately kept by the deputy.
- 8 The deputy to keep an accurate account of all monies received by him on account of the absentee's practice and to hand such monies to the absentee's wife or his other representative on the first of each calendar month. Any clerical work connected with the absentee's practice other than that necessitated by paragraphs 6, 7 and 8 to be done by the absentee's wife or other representative at the absentee's expense.
- 9 Cards to be exhibited in the surgeries (main and branch) of both deputy and absentee clearly stating that the absentee is away on active service and that the deputy is attending to absentee's practice and requesting the patient to inform the deputy that he is a patient of the absentee.
- 10 As far as conveniently possible the patients of the absentee to be seen at the surgeries of the latter and the deputy to hold a surgery daily at the absentee's main surgery.
- 11 The absentee before leaving his practice to make out a list of his private patients with their addresses and to submit such list to the deputy and such list unless questioned within 14 days by the latter to be final evidence that the patients whose names appear on that list are the private patients of the absentee. A copy of such list to be forwarded by the absentee to the said Committee.
- 12 Proper and accurate accounts of the absentee's practice to be kept by the absentee's wife or other representative in the name of the absentee with a request that cheques be drawn in favour of the absentee.
- 13 All accounts of the gross receipts of the absentee's practice to be kept by the absentee's wife or other representative and to be open to the inspection of the deputy or his representative on request at any reasonable hour of the day.
- 14 The absentee should be indemnified against all claims, demands or actions arising out of the negligence or wrongful act or default of the deputy. (It is deemed advisable that an absentee and his deputy be members of a protection society and insured against damages.)
- 15 Subject to the provisions of the next clause the deputy to give the absentee a calendar month's notice of his intention to resign to the absentee's wife or other representative and also to the said Committee. In the absence of an appointment being made by the absentee or his wife or other representative of a fresh deputy the said Committee to make an appointment.
- 16 In case the absentee dies or is killed or returns home (a) in case of attending to his practice the deputy to continue to attend to the absentee's practice for at least a period of 12 months after the date of the absentee's death or of such return home as the case may be; or until the such death or of such return home is disposed of by sale the deputy during this period to continue to receive remuneration as provided in paragraph 4. The deputy to give every facility and information to an incoming or outgoing deputy to give every facility and information to an incoming or outgoing deputy.
- 17 The deputy shall not attend or become personally involved in the treatment of any of the patients on the list referred to in paragraph 11 for a period of one year after the deputy has ceased to carry on the practice or to be involved with the practice of the absentee.
- 18 A Committee to be formed by the practitioners of the district (if thought advisable) the Local Medical War Committee and to have delegated to it by the agreement entered into by the absentee and the deputy such powers as will permit it to deal with all the points in whatever manner it may see fit with the exception of the following: regard to any question affecting the absentee's practice or remuneration or of the same by the deputy and the said Committee to be bound on both parties.

The view of the Central Medical War Committee as expressed with our previously expressed conclusion is that it is possible to embody in one or even two or three distinct schemes plans likely to meet with acceptance in every area. It is however hoped that the publication of the subject will lead to the possibility of some arrangement being made by Local Committees which will differ in detail in general principle will differ in detail according to the wants of the locality.

Medical News.

[illegible]

If on grounds of reprisal we should in any way reduce the rations now supplied to German prisoners of war in this country the German Government propose not only to withdraw the permission for collecting parcels but also to prohibit the receipt of individual parcels the camp ration being then ordered so as to correspond with the measures taken by us. The German Government declare themselves as not averse to the proposal which we communicated to them for the release of all British civilian prisoners of war but they consider that this could not take place on the basis of the release of a similar number of German prisoners by us, as such an exchange would encounter insuperable difficulties in regard to the selection of those prisoners who are to benefit by it. A further communication from us on the subject will now be awaited. To this note His Majesty's Government propose to reply that they cannot accept the proposal to repatriate all the Germans interned in this country in exchange for the British civilians interned in Germany since that would be to send back some 26,000 Germans in exchange for only 4,000 British. They have already proposed to the German Government that all civilians on both sides over 50 should be repatriated and also all those over 45 who are unfit for service in the field with the exception of certain persons to be retained for military reasons. This proposal they will once more press upon the German Government, with the addition that persons so retained shall not exceed 20 on each side. They further propose that the remaining British civilians and an equal number of German civilians shall be interned in a neutral country.

Sir W. BATES: May we take it that the policy of reprisals is abandoned?—Lord JEFFREY CECIL: No, sir, the House must not arrive at any such conclusion. The Government hold themselves perfectly free to retaliate if that proves to be the only way of obtaining justice for our prisoners.

Mr BUTCHER: Why is the number of British civilian prisoners in Germany as compared with the number of interned Germans in this country?—Lord JEFFREY CECIL: There are about 4,000 interned British civilians and 26,000 interned Germans.

MONDAY JULY 17TH

Medical Arrangements in Mesopotamia

Sir HENRY CAMP asked the Secretary for India whether he would take any steps to procure the prompt production of the report by Sir W. Vincent, General Bingley and Mr. Forster upon the medical arrangements for the Mesopotamian campaign and its presentation to Parliament.—Mr. CHAMBERLAIN replied: I have asked the Viceroy to expedite the consideration of the report by the authorities in India and to transmit it to me when it is ready.

and military representatives to medical evidence from private medical practitioners, in the interests both of the Army and the men concerned.—Mr. FORSTER replied: The responsibility for the decisions taken by the recruiting medical boards of course rests with those boards but they have been instructed to give due consideration to medical evidence submitted by civilian medical practitioners regarding the men who have been called up for service. It is not, I think, the case that there has been any general failure to do this, but in view of statements which have been made attention has been called to the point.

TUESDAY, JULY 18TH

The Wounded from the Battle of Jutland

Sir ARCHIBALD WILLIAMSON asked the Secretary to the Admiralty whether, after the battle of Jutland wounded men landed at a naval base in the North were sent by rail to hospitals at Haslar and Chatham, whether a number died on the long railway journey, whether he was aware that on the day in question there were at least 50 beds vacant and held at the disposal of the military authorities within a short distance of the same naval base, and whether he would endeavour to make arrangements with the War Office to obtain temporary use of their unoccupied beds at the nearest suitable hospitals should such an emergency recur.—Mr. MACDONALD answered: The condition of all the wounded landed after the battle of Jutland was carefully examined, and only those men were sent away by rail whose condition justified that procedure. It is not the fact that any of them died, nor is it believed that any of them suffered injury. The arrangements made by the Admiralty would have enabled them, had they thought it desirable, to have accommodated a larger number of patients in the neighbourhood of the landing places than were actually wounded. There was therefore no emergency as my honourable friend seems to suppose. The policy adopted was adopted deliberately by the Medical Department of the Admiralty partly in the interests of sound medical administration, partly for the convenience of men who preferred to be near their depots and their homes.

Medical Arrangement in Mesopotamia

In the course of a statement dealing with the campaign in Mesopotamia Mr. ASQUITH (Prime Minister) said: With regard to the medical provision for the sick and wounded soldier Sir John Nixon, the general who was then in command at the end of last November after the action at Ctesiphon in a report made to the Secretary of State for India from Persia stated that in his opinion the medical arrangements had been satisfactory.

DEADLY NIGHTSHADES

To the Editor of 'THE LANCET'

SIR,—As the berries of the *Atropa belladonna* begin to ripen this month and form a very tempting fruit for children a little later on, the following description of the herb may be useful. "Belladonna has a thick whitish root which is perennial, and sends forth strong, branched, annual, purple coloured stems, from three to five feet high. The leaves are of unequal size, entire, oval, pointed, and stand in pairs on short footstalks. The flowers are of a dark or purplish colour, large, pendant, bell shaped, furrowed, and the lob cut into five segments. The whole plant is covered with fine hairs or down, the flowers appear in June or July, but the berries are not ripe till September, when they acquire a shining black colour." *Geraide (Marhal, 1597)*, after recounting three cases of poisoning from eating the berries, wath wrath and writes "Banish, therefore, these pernicious plants out of your gardens, and all places near to your houses, where children, or women with child do resort." The plant was formerly known as "Dwale," which Dr. A. H. Murray considers as probably from Scandinavian *dval* = sleep, and gives illustrative quotations from *Cuckoo's Blunder*, Chaucer ("Reeve's Tale"), *Piers Plowman*, and others. The most interesting notice of dwale, both from a historical and therapeutic point of view, is that of Thomas Lupton (1585), "Dwale makes one to sleep while he is cut or burnt by cauterizing." I am, Sir, yours faithfully,
Dublin, July 15th, 1916
GEORGE JOY

7 *If I and Others*—Benedict's reagent (S. R. Benedict, *Journal of the Amer Med Assoc*, 1911, 111, 1193) consists of 173 grammes sod or pot citrate, with 200 grammes crystal liad sod carbonate dissolved in 800 c.c of boiling water. After cooling and filtering, 17.3 grammes of copper sulphate dissolved in 100 c.c of water are added, and the whole made up to 1000 c.c. The test for glucose is made as follows: 10 drops of the solution to be tested are added to 5 c.c of the reagent in a test tube, boiled for 1-2 minutes, and allowed to cool. If glucose is present the solution will be filled with a red, yellow, or green precipitate.

COMMUNICATIONS not noticed in our present issue will receive attention in our next

Medical Diary for the ensuing Week.

EDITORIAL NOTICES

It is most important that communications relating to the Editorial business of THE HANNAH should be addressed exclusively "To the Editor," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS not used

MANAGER'S NOTICES

THE INDEX AND TITLE-PAGE TO THE LANCET

January to June, 1918

In view of the Government restrictions upon the supply of paper, and the shortage of paper quite apart from those restrictions, the Index and the Title page to the volume of THE JOURNAL which was completed with the issue of June 24th have been printed separately, and copies have been supplied gratis to those subscribers who have, up to July 20th, intimated to us their wish to receive them. Other subscribers will be similarly supplied, so long as the stock remains unexhausted, on application to the Manager, THE JOURNAL Office, 423, Strand, London, W.C. Such application should please be sent in at once.

Volume and Cases

Volumes for the first half of the year 1916 will be ready shortly. Bound in cloth, gilt lettered, price 16s., carriage extra.

Cases for binding the half year's numbers are now ready
Cloth, gilt lettered, price 2s, by post 2s 4d
To be obtained on application to the Manager, accompanied
by remittance

TO SUBSCRIBERS

TO SUBSCRIBERS

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Office, 423 Strand, London, W.C. are dealt with by them? Subscriptions paid to London or to local newspapers (with none of whom have the Proprietors any connection whatever) do not reach THE LANCET Office, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Office.

Subscribers by sending their subscriptions direct to
their LANCET Office, will ensure regularity in the despatch
of their Journals and an earlier delivery than the majority of
Agents are able to effect.

THE COLONIAL AND ORIENTAL EDITION (printed on this
paper) is published in time to catch the weekly Friday mails
to all parts of the world.

Observations

OF

FIFTY LAPAROTOMIES

PERFORMED FOR GUNSHOT WOUNDS OF THE ABDOMEN

By G. H. STEVENSON, M.B., J. J. M. SHAW, M.D.,
CAPTAINS R.A.M.C. (S.R.);

AND

C. MACKENZIE, M.D., F.R.C.S.,
CAPTAIN, R.A.M.C. (T.C.)

In the following article we give the results of 50 laparotomies on gunshot wounds of the abdomen performed at a casualty clearing station. This clearing station is at present situated roughly about 5½ miles from our nearest front line trenches. The town is frequently bombed, but up to the present has escaped shelling, except on one isolated occasion. A building formerly used as a college for French boys has been adapted to meet the requirements of our patients.

It will be seen from our list of cases that many of the patients were operated on within 5 or 6 hours of their being wounded, our record in this respect being 2½ hours. Many others, however, did not reach us for 12 to 24 hours, and this may seem at a first glance to be a long period of time to cover a distance of 5½ miles. It must, however, be remembered that many factors enter into the question of transit of wounded at the front. Thus, during the winter, the communication trenches may be quite impassable for stretcher parties. In such circumstances the wounded man is kept in the front line trench until darkness makes it possible for his conveyance over exposed ground. Again, the roads leading to this town from the various dressing stations are often heavily shelled, making the transport of wounded impossible for several hours, and long detours have frequently to be made to escape a certain segment of road. It will therefore be easily understood how the time in individual cases must vary enormously, according to the military circumstances prevailing at the moment, and the fact that cases have arrived here in the short periods mentioned must frequently have meant great devotion to duty on the part of the regimental medical officer and stretcher bearers. As an example of what occurs the following case may be quoted. An officer was badly wounded in the abdomen while superintending a working party behind our trenches. In getting him to the first-aid post a bullet passed through one stretcher bearer killing him at once, and lodged in the already badly wounded officer's arm, fortunately doing him little additional harm.

EXPECTANT TREATMENT

As this unit came out to France with the original Expeditionary Force in August, 1914, it might perhaps be of interest to make in the first place a few comments on the treatment of abdominal wounds in the early days of the war, when expectant methods were the routine. Since then we have had considerable alteration in opinion regarding abdominal wounds and the development of the clearing station with its facilities for operation and nursing close to the firing line, has completely altered our outlook in such cases.

Until the beginning of 1915 it was the custom that abdominal cases should be kept, as far as possible, near the spot where the patient received his wound. In practice this meant usually one or other portion of a field ambulance, although in one instance, so firmly had the lessons of the South African War been taken hold, one officer hit in the abdomen refused to be removed from his dug out, and in fact died there in two days time. This being the case, many of the most severe abdominal cases must of necessity have died before they reached the clearing station and any figures we give must be inclined towards optimism, rather than pessimism, for the expectant methods of treatment.

In the pre-operation days at this clearing station we had what we called an abdominal ward where all cases suspected of intraperitoneal injury were placed to undergo the treatment of starvation and morphia. We have from our

admission and discharge books made an analysis of the figures for these cases with the following results—

Total cases	335
Transferred to the base	201
Deaths	134

This gives the low mortality of 40 per cent, which is undoubtedly fallacious in comparison with our operative statistics for the following reasons: 1. Many of the abdominal cases died at field ambulances, and the chief cases we treated here were those not considered to be intraperitoneal when examined at the field ambulance. 2. Evidence is entirely lacking as to the number of real intraperitoneal cases. 3. We have no evidence of the future course of our (so-called) recoveries. If this mortality of 40 per cent is more thoroughly investigated a much more valuable result is arrived at from the point of view of treatment. The following is the analysis of the total deaths with reference to the period of time the man was able to survive his wound—

Total number of deaths	134
Died in 48 hours after admission	84
After 3 days	50

In the light of experience this means that 37 per cent of the patients who died here were able to survive their injuries for over three days, and then died of peritonitis caused by leakage of intestinal contents, which might have been prevented if operative measures had been adopted on admission. It means in fact, that of these 50 cases many lives would have been saved by operative interference and probably a certain number of the 84. Of the 201 cases transferred to the base the majority were evacuated by us after two or three days, which proves, in our opinion, that these were not intraperitoneal.

TYPES OF ABDOMINAL WOUNDS

The following is a very arbitrary classification of the clinical type of abdominal wounds—

Class 1—Those which are without doubt intraperitoneal.—This includes the large class of case with entrance wound in the anterior and exit wound in the posterior abdominal wall, or vice versa, which must of necessity be intraperitoneal and may injure any viscus or structure contained in the abdominal cavity.

Class 2—Those wounds apparently intraperitoneal (from their entrance and exit) which are really extraperitoneal.—The commonest variety of this class is the "side to side" wound of the anterior abdominal wall. In such cases a bullet often follows the planes of the abdominal muscles and does not enter the peritoneum. Such wounds may cause intraperitoneal lesions without perforating the peritoneum (vide Case 28).

Class 3—Those which are doubtful, occurring in the flanks.—This is a very large class, nearly all the wounds of which require an examination under an anæsthetic to investigate their course. Many wounds of this class injure the large bowel only and remain still extraperitoneal, the result being a fecal fistula. Others cause a fracture of the pelvic bones, and others, again, may cause intraperitoneal lesions without actually perforating the peritoneum, as in Class 2. Those which involve the pelvic bones may often produce marked shock.

Class 4—Those wounds which are extraperitoneal but have their entrance in regions situated at a distance from the abdominal cavity.—These include wounds of the buttocks, chest, shoulder, &c., and are very apt to be overlooked. In the region of the anus and fold of the nates it is especially easy to miss the entrance wound of a bullet, which in these regions often amounts to only a tiny slit in the skin.

Class 5—Those wounds involving the peritoneal cavity plus other important extraperitoneal structures—e.g., small intestine plus spine, small intestine plus bladder, stomach plus lung, &c.

CONDITION ON ADMISSION

The easy case from the diagnostic point of view is the severe one. The prostrate patient, pallid, anxious, and cold, with a bluish tinge on the lips which fades into the general grey pallor of the face without the usual line of colour demarcation, the low petulant cry for drinks, the cry of pain on movement of the body or extension of the lower limbs, the site of the wound in abdomen, back, flanks, or buttocks, the pulse rapid, small, and of very low tension, the abdomen hard and moving only slightly on respiration, with dullness all over or in the flanks, and a history of, or the presence of vomiting—these form a group of signs and symptoms by which a diagnosis can often be made at a glance, and for a patient of this sort operation at the

Observations

OF

FIFTY LAPAROTOMIES

PERFORMED FOR GUNSHOT WOUNDS OF THE ABDOMEN

BY G. H. STEVENSON, M.B., J. J. M. SHAW, M.D.,
CAPTAINS R.A.M.C. (S.B.)

AND

C. MACKENZIE, M.D., F.R.C.S.,
CAPTAIN, R.A.M.C. (T.C.)

In the following article we give the results of 50 laparotomies on gunshot wounds of the abdomen performed at a casualty clearing station. This clearing station is at present situated roughly about 5½ miles from our nearest front line trenches. The town is frequently bombed, but up to the present has escaped shelling, except on one isolated occasion. A building formerly used as a college for French boys has been adapted to meet the requirements of our patients.

It will be seen from our list of cases that many of the patients were operated on within 5 or 6 hours of their being wounded, our record in this respect being 2½ hours. Many others, however, did not reach us for 12 to 24 hours, and this may seem at a first glance to be a long period of time to cover a distance of 5½ miles. It must, however, be remembered that many factors enter into the question of transport of wounded at the front. Thus, during the winter, the communication trenches may be quite impassable for stretcher parties. In such circumstances the wounded man is kept in the front line trench until darkness makes it possible for his conveyance over exposed ground. Again, the roads leading to this town from the various dressing stations are often heavily shelled, making the transport of wounded impossible for several hours, and long detours have frequently to be made to escape a certain segment of road. It will therefore be easily understood how the time in individual cases must vary enormously, according to the military circumstances prevailing at the moment, and the fact that cases have arrived here in the short periods mentioned must frequently have meant great devotion to duty on the part of the regimental medical officer and stretcher bearers. As an example of what occurs the following case may be quoted. An officer was badly wounded in the abdomen while superintending a working party behind our trenches. In getting him to the first-aid post a bullet passed through one stretcher bearer killing him at once, and lodged in the already badly wounded officer's arm, fortunately doing him little additional harm.

EXPECTANT TREATMENT

As this unit came out to France with the original Expeditionary Force in August, 1914, it might perhaps be of interest to make in the first place a few comments on the treatment of abdominal wounds in the early days of the war when expectant methods were the routine. Since then we have had considerable alteration in opinion regarding abdominal wounds, and the development of the clearing station with its facilities for operation and nursing close to the firing line, has completely altered our outlook in such cases.

Until the beginning of 1915 it was the custom that abdominal cases should be kept, as far as possible, near the spot where the patient received his wound. In practice this meant usually one or other portion of a field ambulance, although in one instance so firmly had the lessons of the South African War been taken hold, one officer hit in the abdomen refused to be removed from his dug out, and in fact died there in two days time. This being the case many of the most severe abdominal cases must of necessity have died before they reached the clearing station, and any figures we give must be inclined towards optimism rather than pessimism, for the expectant methods of treatment.

In the pre-operation days at this clearing station we had what we called an abdominal ward, where all cases suspected of intraperitoneal injury were placed to undergo the treatment of starvation and morphia. We have from our

admission and discharge books made an analysis of the figures for these cases with the following results—

Total cases	335
Transferred to the base	201
Deaths	134

This gives the low mortality of 40 per cent, which is undoubtedly fallacious in comparison with our operative statistics for the following reasons. 1 Many of the abdominal cases died at field ambulances, and the chief cases we treated here were those not considered to be intraperitoneal when examined at the field ambulance. 2 Evidence is entirely lacking as to the number of real intraperitoneal cases. 3 We have no evidence of the future course of our (so-called) recoveries. If this mortality of 40 per cent is more thoroughly investigated a much more valuable result is arrived at from the point of view of treatment. The following is the analysis of the total deaths with reference to the period of time the man was able to survive his wound—

Total number of deaths	134
Died in 48 hours after admission	84
After 3 days	50

In the light of experience this means that 37 per cent of the patients who died here were able to survive their injuries for over three days, and then died of peritonitis caused by leakage of intestinal contents, which might have been prevented if operative measures had been adopted on admission. It means in fact, that of these 50 cases many lives would have been saved by operative interference and probably a certain number of the 84. Of the 201 cases transferred to the base the majority were evacuated by us after two or three days, which proves, in our opinion, that these were not intraperitoneal.

TYPES OF ABDOMINAL WOUNDS

The following is a very arbitrary classification of the clinical type of abdominal wounds—

Class 1—Those which are without doubt intraperitoneal.—This includes the large class of cases with entrance wound in the anterior and exit wound in the posterior abdominal wall, or vice versa, which must of necessity be intraperitoneal and may injure any viscous or structure contained in the abdominal cavity.

Class 2—Those wounds apparently intraperitoneal (from their entrance and exit) which are really extraperitoneal.—The commonest variety of this class is the "side-to-side" wound of the anterior abdominal wall. In such cases a bullet often follows the planes of the abdominal muscles and does not enter the peritoneum. Such wounds may cause intraperitoneal lesions without perforating the peritoneum (*vide* Case 28).

Class 3—Those which are doubtful, occurring in the flanks.—This is a very large class, nearly all the wounds of which require an examination under an anæsthetic to investigate their course. Many wounds of this class injure the large bowel only and remain still extraperitoneal, the result being a fecal fistula. Others cause a fracture of the pelvic bones and others, again, may cause intraperitoneal lesions without actually perforating the peritoneum, as in Class 2. Those which involve the pelvic bones may often produce marked shock.

Class 4—Those wounds which are extraperitoneal but have their entrance in regions situated at a distance from the abdominal cavity.—These include wounds of the buttocks, chest, shoulder, &c., and are very apt to be overlooked. In the region of the anus and fold of the nates it is especially easy to miss the entrance wound of a bullet, which in these regions often amounts to only a tiny slit in the skin.

Class 5—Those wounds involving the peritoneal cavity plus other important extraperitoneal structures—e.g., small intestine, lung, &c.

CONDITION ON ADMISSION

The easy case from the diagnostic point of view is the severe one. The prostrate patient, pallid, anxious, and cold, with a bluish tinge on the lips which fades into the general grey pallor of the face without the usual line of colour demarcation, the low petulant cry for drinks, the cry of pain on movement of the body or extension of the lower limbs, the site of the wound in abdomen, back, flanks, or buttocks, the pulse rapid, small, and of very low tension, the abdomen hard and moving only slightly on respiration, with dullness all over or in the flanks, and a history of, or the presence of vomiting—these form a group of signs and symptoms by which a diagnosis can often be made at a glance and for a patient of this sort operation at the

earliest possible moment is the only treatment. Even though no pulse can be felt, an operation is not thereby contra indicated, as it gives the last possible chance to the patient. In a few cases the imminence of death is apparent from the mode of respiration, and these are beyond the surgeon's aid. In such cases the abdomen may be quite soft.

The more difficult cases are those in which the above conditions are absent or much modified. On account of the fact that severe intraperitoneal mischief may be caused by a bullet which does not actually enter the peritoneal cavity, the track of the missile is the least important point in decision between operation and observation, except in those obviously slight cases where the muscular and fascial strata are not involved.

If the patient has a fairly strong pulse below 95, is not vomiting, does not show signs of hæmorrhage, can hold his breath for over five seconds without severe pain, permits pressure on all parts of the abdomen except in the immediate vicinity of the wound, and can raise his head voluntarily from the pillow without much discomfort, such a patient is better observed for a few hours, with instructions to the nursing staff to give nothing by mouth, to take an hourly pulse, and to report at once should the patient vomit after being made warm and comfortable in bed. In all cases of doubt it is advisable to anaesthetise, to excise the wound, and to explore with the fingers. If doubt still remains an exploratory laparotomy should be performed.

In a small number of cases the rigidity and tenderness may be localised to one side or one quadrant of the abdomen, and if the appearance and pulse indicate a serious condition laparotomy should be performed, with the expectation of finding the missile lodged in a solid viscus, usually the liver, or in the neighbourhood of the uncovered portion of the posterior wall of the large bowel, with hæmorrhage between the layers of the mesentery. The urgency of such cases is not as great as in those in which infection and hæmorrhage affect the general peritoneal cavity, but operation is the path of greater safety.

TECHNIQUE OF OPERATION

As regards the technique of operation here, this differs little from that in the similar operation of civil practice, but there are a few points which seem worthy of note.

1 Preparation of patient.—(a) As a general rule morphia and atropine are administered hypodermically before operation. We do not usually give saline beforehand, relying on subcutaneous and intravenous injection during and after the operation. It is important to remember that large doses of morphia may have been given before admission to a casualty clearing station. Any dose given by the mouth may be, for all practical purposes, neglected. (b) The "iodine" method is used for the preparation of the skin, except in those cases where the wounds involve a large area, when, after anaesthetisation, the patients are prepared with some carbolic preparation, usually lysol. We invariably endeavour to excise completely both the entrance and exit wound, using, of course, a different set of instruments from those employed in the actual laparotomy. In many doubtful cases it is advisable to explore the direction of the wound before proceeding to the operation, this is especially the case in wounds of the flanks. It is impossible to do this thoroughly without an anaesthetic, as almost invariably the wounds of the different layers of the abdominal wall are not directly one above the other. Thus, the wound in the abdominal muscles may be an inch or more distant from the wound in the skin. The best exploratory instrument is undoubtedly the finger, as by gentle manipulation it is usually possible to trace the wound through the soft tissues with great ease. We usually do this exploration with the naked finger, prior to the final washing up and donning of rubber gloves.

2 Anaesthetic.—Warm ether is the anaesthetic we now use most frequently. To give this we employ an improvised apparatus made out of a thermos flask and a pair of ordinary kitchen bellows which are worked by the anaesthetist's foot. This method was first introduced in No. 17 Casualty Clearing Station, and is excellent in every way. We do not employ a second bottle for chloroform, as we do not think the complex apparatus gives any better results than merely dripping chloroform on the mask, if the patient does not readily go under with ether. It is interesting to note that

while still working with an open acetylene flame and chloroform those operating experienced most unpleasant immediate and remote symptoms, the immediate symptoms being coughing and vomiting, the remote being those of anaemia. This we afterwards discovered was due to the fact that "phosgene" gas was generated by the combination of the two gases burning. Since the introduction of electric light to our casualty clearing station this difficulty has disappeared.

3 Time of operation.—Patients are operated on as quickly as possible, this works out in actual practice at about half an hour after admission. In our opinion it is wrong to wait, no matter how bad the patient may appear, as so often in such cases hæmorrhage and infection are certainly progressing. Many patients have been admitted here with abdomen distended and dull all over, in such cases, on opening the abdomen the blood spouts out as if the vena cava had been cut. In one such case, in which subsequently recovery took place, the iliac vein was actually severed.

4 Incision.—In our experience it is usually better to open the abdomen either in or near the middle line. This incision undoubtedly gives much freer access to the abdomen than any other, and in abdominal wounds one must be prepared for injury to almost any organ contained in the cavity. In one case the wound was in the right lumbar region, and the only intraperitoneal injury found was a perforation of a loop of small intestine in the left iliac fossa, this being one example of many. In such cases it is remarkable how seldom the missile is found and how little harm seems to result from its being left *in situ* (vide Case 33).

5 Intraperitoneal technique.—The wounds in the gut are sewn up with fine thread in two layers, while stitching up continuous tension on the mesentery should be carefully avoided. End-to-end anastomosis is the usual method employed when resection is necessary, except in those cases where several feet of gut have to be removed, when lateral anastomosis is employed, as this is undoubtedly stronger, and in these cases there is considerable tension at the site of anastomosis. Regarding the question of suture *vs* resection, many cases are obviously only suited for the latter, and this, of course, is quicker than the suture of, say, 10 or 12 perforations. It must, however, be remembered that the area of gut surrounding the perforations seems to suffer little harm and is perfectly viable in the great majority of cases. This is more fully dealt with in the section of this article headed "Pathology." Suture in the transverse axis is preferable to the longitudinal, as the latter will undoubtedly decrease the calibre of the bowel, but too much stress need not be laid upon this, as the gut has great powers of expansion, and speed in stitching seems much more important. The above applies only to lesions of the small intestine. Those of the colon present rather a different picture, as in this case the tissues surrounding the injury are much more affected and show a distinct tendency towards secondary infection and sloughing. In many such cases it is possible to excise a wedge shaped portion of gut and then suture, in others a colostomy would seem advisable rather than the risk of a subsequent perforation. In many cases hæmorrhage is present to an enormous extent and the mere evacuation of blood often leads to a great improvement in the symptoms. (This was most marked in Case 31.) In these cases the bleeding point is very seldom found, and the blood often wells through the wound in the parietal peritoneum. This is especially the case in wounds having their entrance in the lumbar region posteriorly. Wounds of the liver are usually packed, occasionally it is possible to suture them (vide Cases 12 and 28). Wounds in the spleen are similarly dealt with. We have not met with many wounds of the kidney, in those cases where the kidney is badly palpated complete removal is, of course indicated, in those where the wound is slight the kidney may apparently be left without much danger, and urinary fistula usually heal up quite well. The gut is carefully washed with saline while outside the abdominal wound, and all fecal material and doubtful lymph gently sponged off. The abdominal cavity is also thoroughly washed out with saline or eusol and mopped dry. Some cases seem to benefit from a quantity of saline being left in the peritoneal cavity. In grossly infected cases we have also tried the injection of ether into the peritoneal cavity. In our opinion the shock produced does

not warrant a continuance of this procedure, although it has given good results in our hands in cases where the infection has been localised, as in appendix cases. Large drainage tubes are inserted into the pelvis, and the flanks as well if the cavity is badly infected.

6 *Closure of the wound*—The abdominal wound is stitched in layers, some silkworm gut sutures being inserted through all coverings except the peritoneum. This we think better than complete through and through suture, which we have also used.

7 *Miscellaneous*—During the operation continuous saline is given by means of Lane's bags, and frequently an intra venous infusion is given in addition. We have also tried the citrate method of blood transfusion but no satisfactory data have yet been obtained. The operating table, although made specially for use in the field, is capable of being used with the patient in the Trendelenburg position.

AFTER-TREATMENT AND SEQUELÆ

The first and most important symptoms to treat after operation are those of *collapse*, and it is necessary in the great majority of cases to have the foot of the bed raised for several hours. When the pulse becomes stronger the head end is raised on two blocks for some time, and as the patient becomes more conscious the Fowler position is gradually assumed, in which he remains until all danger of sepsis has passed. Small salines per rectum (usually with brandy) are given four hourly for the first 24 hours. There is no reason why small sips of water or milk and water should not be given by the mouth at once.

Extreme restlessness is common for the first two or three days, and is often so bad as to call for repeated administration of morphia. It usually increases if the patient is not going to get better, and is exceedingly distressing.

In cases where several hours have elapsed between the time of being wounded and the operation, *distension* is frequently present on admission and in such cases it is advisable to give pituitary extract hypodermically almost immediately after operation. In other cases distension is also common and requires treatment by turpentine enemata, or pituitary extract followed in half an hour by glycerine enema, &c. In our opinion there is no doubt that pituitary extract is the most valuable drug in the after treatment of abdominal cases. It frequently acts like a charm, a motion of the bowels occurring in from half an hour to an hour after injection. Other cases require a glycerine enema to give the desired result. Many patients complain of intense pain following on the administration of pituitary extract, this may often be avoided by giving 1/6 gr. of morphia with the injection, the morphia seems to have little or no effect on the pituitary extract. We invariably use the extract with or without an enema as our first aperient, usually on the third day this depending on the individual patient. In cases where the large bowel has been sutured, and it is undesirable to increase the bowel contents by aperients such as sulphate of magnesia, we have found a preparation of senna to answer very well. This seems to act by softening the fecal material without increasing the bulk.

Bronchitis used to be common before the hot ether administration was introduced, and required the usual treatment. We give a mixture of carbonate of ammonia and iodide of potassium if bronchitis does occur.

Vomiting and hiccough may require stomach lavage. Many such cases respond to treatment with bicarbonate of soda or small doses of tincture of iodine.

Among the later sequelæ we have observed are *pelvic abscess* and *suppuration of the original wound* and *incision*. In grossly infected cases it would seem preferable to use catgut in place of threads in the suture of the deeper layers of the abdominal wound as thread, if infected tends to prolonged suppuration. In cases where the wound is granulating well the skin epithelium may be stimulated by dressings of meat extract such as Lemco. In Case 11 a large pelvic abscess was evacuated on the eighteenth day, after which the patient made a rapid recovery. In another case what might be called 'traumatic insanity' was observed. This case is referred to more fully later. The large pelvic drainage tube is usually removed at the end of 48 hours if no indications to the contrary are present. In several cases where the patients have suffered greatly from hunger or thirst we have allowed 'chewing gum' with marked alleviation of distress.

NOTES ON THE PATHOLOGY OF WOUNDS IN THE HOLLOW VISCERA

Generally speaking, the wounds seem to follow the rule that the exit is larger than the entrance. Thus in Fig 1, if A be the entrance wound and B the exit, B will be considerably greater than A. This is the case in several post-mortem specimens in our possession. There is, however, a great variation in the appearance of the wounds in the different portions of the intestine, which seems worthy of note.

Small intestine—In the small intestine the most marked feature of the wound is the everted mucous membrane giving the characteristic rosette appearance. This is due to contraction of the muscular coats without a corresponding contraction of the mucous and submucous layers. (See Fig 2.) The above is the commonest type of perforation seen, but in many of our cases the bowel, instead of being merely perforated, was completely torn across in several places. This may occur without other lesion or combined with perforation, and is just as often found in bullet as in shell wounds. The tear does not usually extend into the mesentery, but may do so for a fraction of an inch. The appearance is as in Fig. 3.

FIG 1
Diagrammatic transverse section of intestine. The exit wound B is considerably larger than the entrance wound A.

FIG 2
Diagrammatic longitudinal section of intestine showing the everted mucous membrane giving the characteristic rosette appearance.

FIG 3
Diagram showing the less common condition of the intestine torn across.

The explanation of the above is not quite clear, and the following points are mentioned as possible factors in its production. (a) The bullet in traversing the abdomen sets up lateral waves strong enough to rupture the bowel, the so called "explosive" force. The fact that in several cases the bullet has caused complete rupture of the bowel without entering the peritoneal cavity would seem to be in favour of this, as do also those cases where several complete splits occur in a few inches of gut. (b) If we consider that the small bowel is lying in the abdomen anchored in arcs by the mesentery, it is possible that a bullet, hitting at or near the extreme convexity, may cause instead of a perforation an actual rupture, this effect being produced by the muscular action of the bowel plus the tension of the mesentery. Thus in Figs 4 and 4A if a bullet strikes the bowel at A it

FIG 4
Diagrammatic transverse section of intestine to show the different possible directions of the force applied. A bullet striking at A will cause perforation at a tear.

FIG 4A
The same showing the direction of pull of the mesentery.

will cause a perforation, if, however, it strikes at or near B it will cause a complete tear. This is exactly analogous to wounds elsewhere and has been seen especially frequently in wounds of the external aspect of the thigh. This splitting does not seem to take place in the large intestine, so far as our observation goes. (c) Several observers state that the modern rifle bullet owing to the extreme weight of the base compared with the apex, may acquire a "tumbling" motion, and may therefore strike the bowel at one place with its sharp point and at another with its full length, causing complete rupture.

The paralytic distension of the bowel, so often seen, occurs most frequently in resection cases. This is doubtless due to the fact that in such cases a complete rupture occurs in the continuity of the muscular coats, preventing or hindering the passage of peristalsis, and might be mentioned as a reason for suture rather than resection whenever possible. In many cases it would seem that in addition to the injury to the bowel we have a condition of what might be called "bowel concussion," owing to the shock sustained by the sympathetic nervous system, and this may or may not be recoverable from. Operative measures have been suggested as a remedy for these cases, but in our opinion when distension has occurred to any extent the patient is already in a hopeless condition.

Microscopic appearances—Captain J. W. McNee, R.A.M.C. (S.R.), has made for us some sections through the everted edge of the perforation. Those show really remarkably little damage to the surrounding tissues, the epithelium being apparently undamaged almost at the extreme edge of the tear. This is in accordance with post-mortem findings, when the portions sutured are always firmly healed.

Large intestine—Wounds in the large intestine are frequently on the posterior and lateral aspects and are often extraperitoneal, their gravity depending on the ease with which the surrounding devitalised tissues become infected by faecal material, causing virulent spreading cellulitis. The actual wounds have no marked features, and eversion of the mucous membrane is not usually present. The most marked feature observed by us in large intestinal injuries is the large amount of bruising produced, as evidenced by the collection of blood between the peritoneal and internal walls. There is much more tendency to sloughing than in lesions of the small intestine.

Stomach—There is nothing of special importance to note regarding wounds of the stomach, except that there seems a distinct tendency towards infiltration and sloughing of the surrounding tissues. In one of our cases the bullet had nicked a large vessel near the edge of the greater curvature, causing profuse hæmatemesis.

RESULTS

Our results give a recovery rate of 34 per cent. This is low in comparison with a recent splendid series of cases published, and may be accounted for by the fact that we have only kept notes on two cases which showed no intra-peritoneal injury and have not included the results of many exploratory laparotomies performed with negative results, which would have completely altered our figures. It is probable, however, that over a larger number of cases of undoubted peritoneal injury the rate will be somewhat higher, as our series undoubtedly contains an undue proportion of cases of very serious injury. This is borne out in an article by Colonel Outhbert Wallace, O.M.C., and the real recovery rate will probably be between 40 and 50 per cent. In a recent article the writer states that it is not so usual in gunshot wounds of the bowel for the gut to be completely divided, in our experience this is a comparatively common occurrence.

Regarding the question of whether a man will stand operation or not, we take the point of view that if intra-peritoneal perforation of the gut is present he will almost certainly die if not operated on, and that it is right to give him a chance, even though the chance be 1 in 1000. Many of the cases were pulseless on admission, in others the pulse was only felt as a flicker, and yet two at least of this type of case recovered. In the majority of cases it should be considered that we are dealing with young adult males whose physical resistance is at a very high pitch. The cases on which we have considered it undesirable to operate number, so far as we can estimate, only four, and in these cases all the patients died shortly after admission. It must, however, be remembered that unfortunately, such a point of view is only possible at times when the casualty clearing stations are not unduly pressed. In times of stress it will be obviously quite impossible to operate on every case which appears to have little chance of recovery, as this would mean time and labour spent which might be put to a better use in dealing with less seriously injured patients.

A photograph of part of the operating theatre for abdominal, head and "clean" cases is reproduced with this article (see illustration). A smaller theatre and a different

set of instruments, mackintosh sheets, and aprons are employed for any patient exhibiting signs of gas gangrene.

It would be difficult to estimate the improvement which has taken place in the equipment of a casualty clearing station from the operative and nursing points of view since the early days of the war, when a well selected but very

FIG 5

small outfit sufficed for amputations and cleansing operations but nothing more elaborate.

NOTES ON SPECIAL CASES

CASE 7—Practically no abdominal discomfort was experienced by this patient after operation and his wound and incision healed rapidly. On the second day he stated that he had tasted poison in the sips of water given to him. This became a fixed delusion which persisted for five days, and he expressed gratitude each day to the medical officer who did his dressing, and thereby withdrew the poison which his enemies gave him by the month.

CASE 11—This patient, an officer, was so ill on admission that it was open to question whether an operation should be performed at all. He, however, made an excellent recovery from his primary operation, but afterwards developed a large pelvic abscess on the left side which was opened and drained on the eighteenth day. It is interesting to note that before and after his being wounded he consumed quite a considerable quantity of neat rum. The hole in the stomach was roughly the size of a two shilling piece and the abdominal cavity contained a large quantity of stomach contents.

CASE 23—The bullet in this case had not entered the peritoneal cavity, the track could be traced on the examination of the parietal peritoneum as a line of bruising. So that, however, had the lateral force been that there was a crack in the anterior wall of the liver, almost severing a triangular portion of the organ, and there was also a rent in the gastro-colic omentum.

CASE 29—This patient was kept at a clearing station for two months. During that period he did not show the slightest sign of partial obstruction or paresis of the bowel in spite of his serious operation. On the fourth day a large quantity of streptococcal pus welled out of the wound in the left buttock. On the eighth day he developed pneumonia of the right lower lobe and was critically ill for 13 days. His temperature then fell to normal, where it remained for two days. It then rose suddenly to 103°F and he complained of severe pain in the right buttock. On the third day after this rise a swelling of the right buttock became evident and under an anæsthetic 11 ounces of pure streptococcal pus were evacuated. The patient improved considerably, but the suppuration of the original wound of entrance continued. A fortnight later this wound was explored under an anæsthetic and a few small fragments of the perforated iliac bone were removed. An autogenous vaccine was then prepared and the temperature and general condition markedly improved. When he left his temperature was steadily falling and he was eating, sleeping, and feeling well.

CASE 30—This is an excellent example of pure intra-peritoneal hæmorrhage. The patient on admission was extremely ill with a pulse of 120, which was scarcely palpable. He was vomiting continuously, the abdomen was greatly distended and dull almost all over. On opening the peritoneal cavity dark fluid blood spurted out as if a large vessel had been opened by the scalpel. No bleeding point was found and no intestinal or other injury. After operation the pulse dropped in 12 hours to 80 and the patient was transferred to the base on the sixth day for thorough

SYNOPSIS OF CASES

No	Description of wound and missile	Lesions found	Treatment.	A = result B = time between wound and operation	Cause of death.
1	Multiple shrapnel wounds of anterior abdominal wall	Abdomen full of blood and bowel contents Two large perforations of small intestine	Suture of perforation Abdominal lavage and pelvic drainage	A Died in 3 days B 5 hours	General peritonitis Necropsy
2	Entrance wound through right ilium Exit 2 in below and to left of umbilicus	1 Abdomen full of blood and fecal material 2 Two perforations of caecum 3 Several perforations of ileum	Suture of all perforations Large pelvic drainage-tube	A. Died in 3 days B 8 hours	General peritonitis Necropsy
3	Entrance 1 in below and to right of umbilicus. No exit Bullet.	Two small perforations of ileum	Suture of perforations Drainage-tube in right flank	A. Recovery B 2½ hours	—
4	Entrance 2 in to the right of and above umbilicus Bullet.	1 Abdomen full of blood. 2. Eight perforations of ileum and several perforations of mesentery 3 Two perforations of sigmoid flexure	Resection of 3½ ft of ileum (lateral anastomosis) Suture of sigmoid. Pelvic drainage	A. Recovery B 4½ hours	—
5	Entrance in left lumbar region. Exit wound in right iliac region Protrusion of bowel from exit wound Shell fragment	1 Gut completely severed at ileo-caecal junction 2. Multiple perforations of ileum in 2 ft. immediately above caecum	Resection of 2 ft. of ileum Suture of caecum Anastomosis of ileum and sigmoid	A. Died in 2 hours B 3 hours	Hæmorrhage and shock No necropsy
6	Entrance left buttock Exit wound just below umbilicus Bullet	1 Three perforations of ileum 2. Perforation of bladder	Suture of perforation of intestine suprapubic cystotomy	A. Died in 48 hours. B 4 hours	Hæmorrhage and shock No necropsy
7	Entrance right buttock. Exit 3 in. below to left of umbilicus Shell fragment.	Eight perforations in small intestine One perforation in caecum Iliac vein torn large intraperitoneal hæmorrhage.	Resection and suture Lateral anastomosis	A. Recovery B 7½ hours	—
8	Entrance 1 in. above and to left of umbilicus Exit right hip Bullet	Six perforations in small intestine larger retroperitoneal hæmorrhage.	Suture of perforations	A. Died in 36 hours B 3½ hours	Shock and hæmorrhage No necropsy
9	Entrance below and to right of umbilicus No exit. A loop of torn bowel protruding Bullet	Five perforations of jejunum 1 ft. of lower part of ileum blown to pieces perforation of bladder	Resection and suture	A Died in 4 hours B 4 hours	Operation performed only because extruded bowel was being strangulated Patient never rallied
10	Entrance 1 in. below twelfth rib in right mid-axillary line. No exit Bullet	Abdomen full of blood and fecal material large tear in colon at hepatic flexure extensive retroperitoneal hæmorrhage	Suture of tear in colon	A. Died in 36 hours B 3½ hours	Necropsy Bullet found in twelfth dorsal vertebra with point actually in spinal canal Fracture of twelfth rib
11	Missile had passed through right upper arm into abdomen in right clavicular line at level of eighth rib and lay under skin in left hypochondriac region Shrapnel bullet.	Rupture of liver large rent in anterior wall of stomach tear in gastro-colic omentum with bleeding vessels	Suture of stomach Liver packed Bleeding vessels tied	A. Recovery after second operation for pelvic abscess B 5 hours	—
12	Transverse laceration in epigastric region Protrusion of portion of stomach and transverse colon Portion of high-explosive shell.	Laceration of liver a portion of the anterior border being almost completely severed.	Removal of loose portion of liver Catgut suture of liver Suture of wound Abdominal drainage.	A Recovery B 5 hours	—
13	Transverse laceration of abdominal wall 8 in long in epigastric region Protrusion of stomach transverse colon and large portion of great omentum Portion of high explosive shell.	Large portion of great omentum ingrafted with mud and portions of stone This was gangrenous	Portion of lacerated omentum removed Edges of the wound pared Large drainage tube inserted	A. Recovery B 24 hours	—
14	Entrance below costal margin in the region of the gall bladder Exit right lumbar region just below twelfth rib Exit wound large and (?) injury to vertebrae Bullet	Abdomen full of blood Localised peritonitis round large stellate rupture of under surface of liver	Liver packed Abdomen washed out and drained	A. Died in 10 hours B 30 hours	Necropsy A very large retroperitoneal hæmorrhage. Large amount of blood clot in abdominal cavity Fracture of twelfth rib and vertebrae Patient had only one kidney (enormously enlarged)
15	Entrance between fifth and sixth ribs 1 in to right of sternum No exit. Bullet.	Ruptured liver one perforation transverse colon one in jejunum; one in caecum	Suture of perforations Liver packed	A. Died in 6 hours B 4½ hours	No necropsy Death from shock and hæmorrhage
16	Entrance anterior abdominal wall on level with umbilicus in mid-clavicular line No exit. Shell fragment.	Twenty perforations small intestine Mesentery torn in two places	Suture of one perforation of ileum and one of pelvic colon Double resection and one end to end and one lateral anastomosis	A. Died in 12 hours. B 6 hours	No necropsy Shock and hæmorrhage
17	Entrance upper portion hypogastric region left side (large and lacerated) No exit Shell fragment	Numerous perforations and complete tears in small intestine Abdomen full of blood.	Resection of 4 ft of small intestine Lateral anastomosis	A. Died B 16 hours	Shock and hæmorrhage. No necropsy
18	Entrance over ninth rib in left posterior axillary line No exit. Bullet	Abdomen full of blood. Laceration spleen and liver; two tears in stomach and a long tear in transverse colon	Suture of tears in stomach and colon Liver and spleen packed	A. Died in 6 hours B 6½ hours	Necropsy Left pleural cavity full of blood Bullet lying just below external surface of right lobe of liver Principally lung condition
19	Entrance right costal margin near mid Poupert plane Another wound (?) penetrated apex of right lung Shrapnel.	Tip of gall bladder cut off transverse colon bruised one perforation of jejunum	Gall bladder sutured also perforation in jejunum Bruised portion of colon invaginated Chest wound examined and found penetrating Liver packed	A. Died in 24 hours after profuse hæmoptysis B 5½ hours.	—
20	Entrance left posterior lumbar region over eleventh rib; exit right hypochondriac region Bullet	Abdominal cavity full of blood Large stellate crack on under surface of liver bleeding freely	—	A. Died a few hours after operation B 13 hours	Chiefly hæmorrhage Bullet had traversed the body of the dorsal vertebra No necropsy

SYNOPSIS OF CASES—(Continued)

No	Description of wound and missile	Lesions found	Treatment	A = result. B = time between wound and operation.	Cause of death
21	Entrance right hip Bullet lay under the skin below left iliac crest	Blood in urine on passing catheter. Abdominal cavity full of blood. Small loop of intestine in pelvis blown to pieces. Several other perforations. No injury to bladder found.	Resection end-to-end anastomosis	A Died B 15 hours	Shock and hæmorrhage
22	Five wounds in left posterior lumbar region. Shell fragments	Five perforations small intestines. Small portion of shell embedded in bowel wall.	Suture of perforations	A Recovery B 18 hours	—
23	Entrance left lumbar region on level with umbilicus. Exit low down right lumbar region. Bullet	Four tears in transverse colon two in jejunum one in cæcum	Suture of perforations	A. Recovery B 5 hours	—
24	Entrance inner side of left anterior superior spine. Exit left buttock. Bullet	Large intraperitoneal hæmorrhage. No intestinal injury found.	Pelvic drainage	A. Recovery B 6 hours	—
25	Particulars of wound not kept. Bullet	Multiple complete tears of small intestine. Several isolated perforations.	Resection of 18 in small intestine. Suture of perforations.	A Recovery but had a fecal fistula. B ?	—
26	Ragged tear in right lumbar region. Shell fragment.	Abdomen full of blood. Extensive bruising of colon at hepatic flexure. Spouting artery in mesentery.	Spouting vessel tied. Pelvic drainage.	A Recovery but had a fecal fistula. B 6 hours	—
27	Ragged wound above right iliac crest. Partial paralysis right leg. Bullet (ricochet)	Some hæmorrhage in abdominal cavity. Large retroperitoneal hæmorrhage and extensive bruising of cæcum.	Abdomen washed out and stitched up.	A. Died in 12 days B 5½ hours	Necropsy: Two large rents in posterior aspect of ascending colon. Extensive cellulitis, septic broncho-pneumonia both lungs. Several lumbar nerves cut.
28	Entrance right epigastric region. Exit left hypochondriac region. Bullet	Split 2½ in long anterior border of liver. Rent in gastro-colic omentum. Several vessels spouting. Bullet had not entered peritoneal cavity.	Liver stitched. Bleeding vessels ligatured.	A Recovery B 4½ hours	—
29	Entrance left buttock. Shrapnel bullet lying under skin above right anterior to superior spine. Shrapnel bullet.	19 perforations of small intestine. Generalised peritonitis. Large quantity of blood in abdomen. Retroperitoneal hæmatoma.	Double resection and end-to-end anastomosis.	A. To base. Suppuration of entrance wound persisting. B 4½ hours.	—
30	Entrance right posterior iliac region. No exit. Shrapnel bullet.	Peritoneum full of dark blood. No injury to hollow viscera found.	Pelvic drainage.	A. Recovery B 3 hours	—
31	Entrance left buttock. Exit right hypogastric region. Knuckle of bowel protruding. Bullet.	Abdomen full of blood. Multiple perforations and ruptures of small intestines.	Double resection and suture.	A. Died in 2 hours B 7½ hours	Shock and hæmorrhage. No necropsy.
32	Entrance right buttock. No exit. Large swelling in region of right inguinal canal. Shell fragment.	Large fragment of shell in congenital hernia sac six large perforations in ileum near junction with cæcum. Laceration of cæcum and appendix.	Resection end to end anastomosis. Appendix removed. Cæcum sutured.	A. Died in 24 hours B 6 hours	Shock and hæmorrhage. Iliac bone badly shattered.
33	Entrance 2 in. below ninth costal cartilage. Bullet.	Small perforation near edge of greater curvature of stomach. Large vessel spouting.	Purse-string suture round stomach perforation. Bullet afterwards removed from liver.	A. Recovery B 14 hours	—
34	Entrances high up in right hypochondrium. Bullet lying under skin on right side between tenth and eleventh ribs behind.	Small quantity of blood in peritoneum. Bullet passed through liver.	Drainage of peritoneum.	A. Recovery B 3 hours	—
35	Entrance anterior abdominal wall right hypochondrium. Exit posterior abdominal wall close to left side third lumbar vertebra. Revolver bullet.	Two tears in transverse colon two perforations of duodenum.	Suture of all perforations. Pelvic drainage.	A Died in 3 days B 2 hours	Necropsy: Localised peritonitis. Large retroperitoneal hæmorrhage.
36	Entrances right umbilical region. Exit right lumbar region. Bullet.	Abdomen contained blood and intestinal contents. Two complete ruptures of small intestine.	Resection of 1 foot of intestine end to end anastomosis.	A Died in 3 days B 10 hours	General peritonitis. Necropsy.
37	Entrance right umbilical region. No exit. Shell fragment.	Small knuckle of intestine protruding. 14 perforations and ruptures of ileum.	Resection of 4 ft of bowel end to end anastomosis.	A Died in 14 hours B 4½ hours	Shock and hæmorrhage. No necropsy.
38	Entrance McBurney's point. Exit right buttock. Bullet.	Severe bruising of cæcum. Large retroperitoneal hæmorrhage. No intestinal perforations found.	Drainage of right iliac fossa.	A Died in 48 hours B 5 hours.	General peritonitis. Portion of cæcum had sloughed causing fecal fistula. Small ulcer in upper part of ileum.
39	Entrance left buttock. Exit left iliac region. Shell fragment.	Two large tears in sigmoid four rents small intestine fracture of pelvis.	Resection of 2 feet of small intestine. Suture of sigmoid. Pelvic drainage.	A Died in 4 days suddenly B 10 hours	Necropsy: Localised peritonitis. Heart dilated and flabby. Extensive mitral disease.
40	Entrance posterior abdominal wall over twelfth rib on left side. No exit. Shell fragment.	Two large rents in descending colon one rent in jejunum large shell fragment lying on the aorta behind peritoneum.	Suture of jejunum. Colostomy. Pelvic drainage.	A. Died in 5 days B 11 hours	General peritonitis. Necropsy.
41	Entrance anterior abdominal wall left lumbar region. Missile lying below twelfth rib left side. Also wound of chest ? penetrating. Shell fragments.	Protrusion of knuckle of bowel from entrance wound. Ileum torn in two places.	Suture of perforations. Pelvic and flank drainage. Missile excluded.	A Died in 3 days B 4 hours	Necropsy. Slight localised peritonitis left iliac fossa. Portion of shell in right lung. Hæmorrhage.

SYNOPSIS OF CASES—(Continued)

Description of wound and missile	Lesions found.	Treatment.	A = result. B = time between wound and operation.	Cause of death
Entrance posterior abdominal wall, left lumbar region. Exit anterior abdominal wall, left lumbar region. Also bullet wound of right arm. Entrance posterior abdominal wall, right lumbar region. Shell fragment.	Abdomen full of blood. Two large tears in sigmoid severe bruising round tears. Solid fecal matter lying free in pelvis. Missile had penetrated back of hepatic flexure. Two perforations of ileum in a loop lying in left iliac fossa.	V-shaped resection of affected portion of sigmoid.	A. Recovery B 5 hours.	—
Entrance costal margin, left epigastric area. Exit right loin. Bullet (shrapnel).	Rupture of liver. Wound through right kidney. Abdomen full of red blood.	Liver and kidney packed with gauze.	A. Died in 8 days having developed fecal fistula and severe diarrhea. B 20 hours.	Necropsy Slight adhesive peritonitis. Right lobar pneumonia.
Entrance right posterior lumbar region. Bullet lying under skin in left umbilical area. Shrapnel. Entrance right buttock. Exit left umbilical region. Bullet.	One perforation of jejunum, three of ileum and three in caecum, and two in transverse colon. Abdomen full of blood. 11 perforations and tears of ileum one perforation of caecum. Caecum badly bruised. Severe bruising of transverse colon.	All perforations sutured. Shrapnel bullet removed.	A. Died in 3 days, after removal of packing. B 4 hours.	Secondary hemorrhage. Necropsy Abdomen contained large blood clots. Complete transverse splitting of right kidney. Necropsy General peritonitis. Large retroperitoneal hemorrhage. Old adherent pericarditis.
Entrance left buttock. Exit left iliac region. Shell fragment.	Large intraperitoneal hemorrhage. Comminuted fracture of left iliac bone.	Drainage.	A. Died in 30 hours. B 5 hours.	Necropsy Large peritonitis. Large retroperitoneal hemorrhage. Old adherent pericarditis.
Entrance posterior abdominal wall left lumbar region. No exit. Shell fragment. Multiple wounds of face, arms, and legs.	Protrusion of small piece of omentum from wound. No intestinal injury. Hematomas in mesentery. Omentum torn and bleeding.	Vessels in omentum ligatured.	A. Died in 2 hours. B 5 hours.	Necropsy Large portion of anterior wall of transverse colon had sloughed. Abdomen full of fecal material.
Entrance posterior dorsal region, over tenth rib. No exit. Shell fragment.	Abdomen full of blood. Missile had passed through liver and was lying in anterior abdominal wall.	Liver packed with gauze.	A. Died in 12 hours. B 4 hours.	No necropsy Shock and hemorrhage.
Entrance wound in umbilical area. No exit. Shell fragment.	Abdomen full of blood and fecal matter. Large tear in transverse colon and caecum. Two tears in small intestine. Extensive bruising of caecum.	Suture of transverse colon and small intestine. Artificial anus at caecum.	A. Died in 3 hours. B 5 hours.	No necropsy Shock and hemorrhage.

X ray examination. He was then exceedingly well. A subsequent report from the base stated that the patient made an excellent recovery and that no further X ray examination was considered necessary.

CASE 33.—This patient was admitted with a small wound in the epigastric area which did not seem to perforate. In a few hours however he vomited a large quantity of bright red blood and became so ill that immediate operation was decided on. On opening the abdominal cavity nothing at first was found until a thorough examination of the anterior wall of the stomach revealed a tiny puncture near the edge of the greater curvature which just admitted the point of a probe. A large vessel was partially severed and was pumping its contents into the stomach. No bullet could be found. The patient did perfectly well. The bullet was afterwards located by X rays in the liver and removed by a surgeon at the base.

The following analysis of the foregoing table has been made in order to emphasize certain points of interest in the series of operations.—

Site of the Lesion in the 17 Cases which Recovered

(a) Wounds of the small intestine alone—4 cases (3, 22, 25 and 29).

Treatment adopted—Suture alone in 2 cases (3 and 22). Resection and suture in 1 case (25). Double resection in 1 case (29).

(b) Wounds of the small and large intestine—3 cases (4, 7, and 23).

Treatment—Resection of small intestine suture of large intestine (Case 4). Resection and suture (Case 7). Suture alone (Case 23).

(c) Wounds of the large intestine alone—1 case (42).

Treatment—V shaped resection of the sigmoid.

(d) Wounds of the stomach and liver—2 cases (11 and 33).

Treatment—Suture of perforation in stomach liver tear packed (Case 11). Suture of perforation in stomach (Case 33).

(e) Wounds of the liver—3 cases (12, 25 and 31).

Treatment—Pent in liver sutured in 2 cases (12 and 25).

Drainage of peritoneum only (Case 31).

(f) Intraperitoneal hemorrhage without injury to a hollow viscus—3 cases (2, 25 and 30).

Treatment—Bleeding point in mesentery ligated (Case 25).

Drainage of peritoneum bleeding point not located (Cases 2 and 30).

(g) Wound of the omentum—1 case (15).

Treatment—Excision of the prolapsed portion and wound sutured.

Summary

Cases that recovered	17
Parts involved	
Small intestine alone	4
Small and large intestine	3
Large intestine alone	1
Stomach and liver	2
Liver	3
Hemorrhage without perforation of intestine	3
Wound of omentum	1
Total	17

A fecal fistula occurred in 3 cases. (1) Small gut (Case 25) recovered, (2) colon (Case 25) recovered, (3) colon (Case 43) died. Sloughing of the colon in 1 case (45), died. Secondary operation for localised abscess 1 case (11) recovered. Perforation of the bladder with wounds of the intestine 2 cases (6 and 9), both fatal.

Site of the Lesions of the 33 Fatal Cases

1. Wounds of the small gut alone—10 cases. In 6 of these extensive intraperitoneal hemorrhage was present.

2. Wounds of the small and large intestine—9 cases as follows. Small gut and caecum, 2. small gut and transverse colon, 3. small gut and sigmoid, 1. small gut and transverse colon, 1. small gut and descending colon, 1, and small gut and hepatic flexure, 1. In 6 free hemorrhages had occurred.

3. Wounds of the large intestine alone—3 cases. hepatic flexure ascending colon and caecum.

4. Wounds of the bladder and small intestine—2 cases.

5. Wounds of the liver alone—3 cases.

6. Wounds of the liver associated with other viscera—4 cases.

Stomach and transverse colon, 1. liver, spleen and jejunum, 1. liver and kidney, 1.

One case of injury to the omentum and one of fracture of the pelvis with intraperitoneal hemorrhage bring the total of fatal cases to 33.

The cause of death in the 33 fatal cases was found to be as follows. 1. General peritonitis—10 cases. The average time of survival after operation was 3 days. 2. Hemorrhage and shock—19 cases. Time of survival varied from 2 to 48 hours after the operation. 3. Lung conditions—2 cases.

(a) hæmoptysis, and (b) broncho-pneumonia and cellulitis
4 Secondary hæmorrhage (kidney)—1 case 5 Sloughing of the gut—1 case

In conclusion, we wish to express our indebtedness to Surgeon General Sir Anthony Bowlby, K.C.M.G., K.O.V.O., A.M.S., consulting surgeon, for valuable help and encouragement, and to Lieutenant-Colonel J.W. Leake, O.M.G., R.A.M.C., for permission to publish this article

ON THE ADVANTAGE OF USING A BROTH CONTAINING TRYPSIN IN MAKING BLOOD CULTURES

By S. R. DOUGLAS, M.R.O.S., L.R.O.P. LOND.,
CAPTAIN I.M.S. (RETIRED); FIRST ASSISTANT BACTERIOLOGICAL
DEPARTMENT, MEDICAL RESEARCH COMMITTEE,

AND

L. COLEBROOK, M.B., B.S. LOND.,
CAPTAIN R.A.M.C. (T) ASSISTANT, BACTERIOLOGICAL DEPARTMENT,
MEDICAL RESEARCH COMMITTEE

(From the Inoculation Department, St Mary's Hospital, W.)

It is now generally recognised that at times very important information may be gained by making cultures from a sample of blood drawn from a vein, for by this simple procedure it is often possible to make a definite diagnosis, especially in cases of obscure fevers. There is little doubt that this method of investigation would be much more frequently adopted if positive results could be obtained in a larger percentage of cases, and if the presence or absence of growth could be more rapidly determined. Even if living microbes are present in the sample of blood obtained from the vein it is quite possible that no growth will be detected in the cultures made from it, or the growth will be so delayed that for several days it will be unrecognised either by direct examination or by subculture.

The following factors are certainly of importance as causes of some of the failure and much of the delay.

1 When blood is added to broth clotting soon takes place and the fibrin meshwork formed catches up any microbes—as has been demonstrated by Jousset—together with the cellular elements of the blood. The fibrin contracting, a firm mass is formed which usually sinks to the bottom of the tube. If, as is generally the case, only very few micro-organisms are present it is more than probable that, even if these organisms multiply in the clot, growth would appear in the surrounding broth only after a considerable interval.

2 Wright's recent researches have shown that the leucocytes are capable of wandering through the fibrin meshwork forming the clot and are frequently attracted towards any microbes present, which they attack and often kill, so that there is present in such clots a condition favourable to killing off any microbes that may be present.

3 Again it is very generally recognised that the blood fluids are antibacterial, thus, in respect of certain organisms the serum has very considerable bactericidal properties, and almost every organism is affected by the opsonic properties of the serum and rendered by it more easily taken up by the leucocytes. These properties of the blood fluids may play an important rôle in preventing the rapid growth of organisms in blood cultures.

4 Another property which belongs to the blood fluids is that of inhibiting the growth of microbes, although they may not be actually bactericidal. This property largely depends on the concentration of the serum and differs markedly in individuals, being often very marked in the infected.

From time to time recommendations have been made to improve the technique of blood cultures, it having been stated that by this or that procedure a larger percentage of successes or quicker results were obtained. When these methods have proved successful it is always found that the three factors mentioned above—namely, the formation of a firm clot, the bactericidal action of the blood, or the inhibitory action of the serum—have to some degree been modified. For instance, it has been recommended that a large quantity of broth should be used and that only a small quantity of blood should be added to each flask and this simple device by lessening the antibacterial action of

the blood, is certainly attended with considerable success. Again, special media have been advocated—for instance, the employment of bile as a medium in making the blood cultures for the diagnosis of typhoid fever and allied infections. By this method it has become possible to be certain of obtaining a positive result within 36 or 48 hours in all cases in which the blood culture is made during the early stages of the disease. Let it be here noted that the bile prevents the blood from clotting and completely abolishes all the bacteriotropic actions of the serum. Bile as a medium is only of use, however, when the organisms to be cultivated belong to the typhoid-coli group, which flourish on its constituents, it is strongly antagonistic to the growth, or even the life, of most other organisms.

Considering these various facts, it appeared that before discovering an ideal medium in which to make blood cultures it was necessary to find some substance which (1) prevented the clotting of the blood, (2) destroyed the bactericidal action of the serum and the activities of the leucocytes, (3) destroyed the inhibitory power of the blood fluids with regard to the growth of the organisms, and (4) which favoured, or at any rate did not hinder, the growth of the pathogenic organisms. The possibility that trypsin was such a substance was suggested by certain experiments recently reported and which are here outlined. While making researches on the treatment of suppurating wounds Wright found that when the antitryptic power of the serum present in the wound was neutralised by the trypsin set free by the breaking down of the leucocytes of the pus, many organisms grew luxuriantly which were quite incapable of multiplying when the wound contained a serum rich in antitryptic power.¹ Emery, continuing these investigations showed that by neutralising the antitryptic power of the serum with trypsin the bactericidal action and other bacteriotropic properties of the serum were destroyed. From the same laboratory came the fact that when sufficient trypsin was added to the blood to neutralise the antitryptic power of the blood fluids no clotting took place.

It was therefore determined to carry out a series of experiments in order to confirm these results and at the same time to plan the experiments in such a way that the results obtained would show if a broth containing trypsin would be suitable for use in making blood cultures. The trypsin used throughout these experiments was the compound solution of trypsin of Messrs Allen and Hanburys² as it has been found that this solution is very constant in strength. Further, in respect of its sterility, this preparation may generally be relied upon, although it is advisable to test samples from time to time. One contaminated batch has been met with in the course of these experiments, but careful testing of more than ten other batches, both aerobically and anaerobically has given no growth of organisms. By means of a series of experiments it was shown that a volume of this trypsin diluted 1 in 30 was capable of preventing an equal volume of blood from clotting, and also completely destroyed the bactericidal action of the blood. The details of one of these experiments are here given to demonstrate the method used and the results obtained, which were very constant.

A typhoid broth culture 24 hours old was diluted 1 in 1 million times, and 10 c mm of this dilution were planted out on to the surface of agar slopes. Tubes 1 and 2 gave 7 colonies and 11 colonies respectively, which gives an average of 9 colonies in 10 c mm of 1 in 1 million dilution of the culture.

10 c mm of 1 in 1 million dilution of the culture were then mixed with 10 c mm of blood on a sterile slide, and after a few seconds 10 c mm of a dilution of trypsin were added and the whole thoroughly mixed. This mixture was then drawn up into the capillary portion of a Wright's bactericidal tube the reservoir of which had been previously filled with sterile broth. After the tube had been incubated for four hours at 37° C the contents of the capillary portion were drawn up into the broth filled reservoir, a note being made as to whether clotting had occurred in the mixture. The tubes were again incubated for 24 hours and then examined for presence of growth (Table I).

Further experiments were carried out to find the effect of various dilutions of trypsin on the clotting time of the blood. The result obtained was that a dilution of trypsin of about 1 in 30 completely inhibited the clotting power whereas

¹ THE LANCET Oct 30th 1915 p 523
² Not 'Liquor Trypsin Co.'

weaker dilutions had the effect of making the blood clot very much more rapidly

TABLE I.

No. of tube	Dilution of trypsin	Result as regards clotting	Result as regards growth

7	1 in 75		
8	1 in 100		
Broth control	None		"

The method used to demonstrate these facts was to fill in a series of capillary tubes with equal volumes of blood and the dilution of trypsin solution controls with salt solution in place of trypsin being also put up. When drawing up these mixtures into the tubes a few bubbles small enough to move freely in the bore were introduced. By tilting the tube the moment of clotting could be easily ascertained from the fixation of these air bubbles and this conclusion was then confirmed by blowing out the contents of the tube into a vessel of water. The experiments were carried out at room temperature. An example is given in Table II.

TABLE II.

Contents of tube.	Time of clotting
1 vol. blood and 1 vol. salt solution.	4 minutes 50 seconds
1 " 1 " 1 in 200 dilution trypsin	3 " 25 "

1 " " 1 " 1 in 50 "	3 " 30 "
1 " " 1 " 1 in 20 "	Clotting complete & inhibited

The next point to be investigated was the effect of trypsin on the opsonic power of the serum, and it was again found from experiments similar to that given in detail below that strengths of about 1 in 30 were necessary to inhibit this bacteriostatic property of an equal quantity of serum.

The method used was as follows. A series of tubes were filled in with a mixture made by taking 1 volume of washed corpuscles, 1 volume of serum, 1 volume of staphylococcus emulsion and 1 volume of trypsin solution or, in the case of the control, 1 volume of salt solution. These tubes were then incubated for 15 minutes after which films were made stained with carbol-thionin and the average number of staphylococci per leucocyte estimated. The results obtained in one such experiment are given in Table III.

TABLE III.

Tube	Control	1 vol. corpuscles	1 vol. serum	1 vol. staphylococcus emulsion	1 vol. normal salt solution	Result
1	2-1	1	1	1	1	= 300 cocci per cell
2	1	1	1	1	1	= 300 "
3	1	1	1	1	1	= 300 "
4	1	1	1	1	1	= 300 "
5	1	1	1	1	1	= 300 "
6	1	1	1	1	1	= 100 "
7	1	1	1	1	1	= 0-10 "

It may be here noted that the antitryptic power of normal serum is just neutralised or very nearly neutralised, by an equal volume of a 1 in 30 dilution of the trypsin used.

Further experiments were carried out to ascertain whether solutions of trypsin destroyed the power of the serum to inhibit the growth of organisms and it was found that in sufficient strength trypsin totally removed this property of the serum.

The method used to demonstrate this was to take in the one case a quantity of fresh warmed serum, and in the other a similar quantity of warm serum to which 5 per cent of a trypsin solution had been added. In each case of these with a small (and equal) number of streptococci and then all sufficient concentration of agar solution to convert the mixture into a jelly on cooling. After this mixture had been incubated at 37°C and the number of colonies were counted at intervals. The details of one such experiment are here given.

Tube 1.—700 c.mm. of fresh serum were mixed with 10 c.mm. of 1 in 100,000 dilution of a 24-hour-old broth

culture of streptococcus progenes, and warmed to about 45°C in a water bath.

Tube 2.—55 c.mm. of trypsin solution were added to 665 c.mm. of fresh serum, and with this were mixed 10 c.mm. of 1 in 100,000 dilution of the streptococcus used in Tube 1, this mixture being also warmed to 45°C.

Tube 3.—700 c.mm. of broth were mixed with 10 c.mm. of the streptococcus culture.

To each of these tubes were then added 100 c.mm. of a 4 per cent. solution of agar in normal saline which had been melted and cooled to 47°C. The tubes were now rapidly cooled to make their contents set, and afterwards incubated at 37°C (Table IV).

TABLE IV.

	Number of colonies after 1 hour.	Number of colonies after 22 hours.

* Very minute

The result of all these experiments, which confirmed and amplified the findings of Wright and his fellow-workers strongly suggested that a broth to which sufficient trypsin had been added to make sure that the antitryptic power of the blood was neutralised would be a pre-eminently suitable medium to use for making blood cultures. Taking into consideration the fact that the antitryptic power of the serum is generally very much increased in the infected, it was decided that the proportion of trypsin in the broth should be not less than 5 per cent. Tubes containing 5 c.c. of such a broth could be relied upon always to neutralise the antitryptic power of 1 c.c. of blood. Before passing on to make blood cultures it was ascertained that all the ordinary organisms grew readily in this medium. Staphylococcus streptococcus (several strains) pneumococcus B typhosus B paratyphosus A and B, B pyocyaneus vibrio cholerae, micrococcus melitensis, B perfringens, and B anthracis, all gave abundant and rapid growths when planted in 5 per cent of trypsin broth.

The first series of blood cultures were made from animals. The animals used in these experiments were rabbits which had been infected by intravenous inoculations of staphylococcus or streptococcus. Samples of blood were drawn off from the heart at varying intervals after infection and distributed into a series of tubes, some of which contained 5 per cent trypsin broth the others simple broth. The details of these experiments are given in tabular form. (Table V)

TABLE V.—Showing the Result of Blood Cultures made from Rabbits.

Rabbit 1. Inoculated with 0.5 c.c. of a 24-hour old broth culture of staphylococcus into the aural vein. 5 c.c. of blood drawn off from the heart 4 days after the inoculation. 0.5 c.c. of blood added to each tube of medium, 4 tubes of trypsin broth and 4 tubes of simple broth (5 c.c.). These tubes were incubated at 37°C and examined at varying intervals.

These results demonstrate that the use of trypsin broth was of distinct advantage in each case. Growth was detected earlier in almost every experiment and also in most cases occurred in a larger percentage of the tubes. In one experiment growth was detected after incubation for 24 hours in two out of five of the trypsin tubes, but in a similar number of cultures made in simple broth no growth was detected even after the lapse of five days.

Table VI shows the results obtained in a series of blood cultures made on patients. The usual technique was employed—blood being drawn off from a vein at the bend of the elbow and planted into a series of tubes.

TABLE VI

Here again the results obtained in every case show advantages in using trypsin broth, either in respect of the number of tubes in which growth was found or as regards the time taken for growth to appear. In one case, for the details of which we have to thank Dr H. M. Woodward, no growth appeared at all in the tubes containing ordinary broth, whereas abundant growth was present in every trypsin broth tube at the end of 24 hours. It is also to be noted that three of the blood cultures here quoted as demonstrating the value of trypsin yielded a growth of paratyphoid bacilli (*B. paratyphosus* A) and in every case within 24 hours. Such a result is similar to that which would have been obtained by using bile as the medium for blood culture. Further the fact that paratyphoid bacilli as well as staphylococci and streptococci were all recovered more easily by the use of trypsin lends support to the idea that this procedure, depending, as has been shown, upon elimination of the antibacterial properties of the blood, has a wide application in the investigation of disease and is not especially advantageous for any one group of pathogenic organisms.

Having from these results satisfied ourselves that the use of trypsin broth in making blood cultures was of a very distinct advantage it became an important practical point to ascertain if such a broth retained its properties on keeping. The following experiments were therefore carried out.

Five per cent. of trypsin solution was added to broth on April 8th and kept for several weeks at laboratory temperature. Its tryptic power was determined on April 8th, and at intervals subsequently, by making from it a series of dilutions and mixing one volume of each of these with one volume of milk to which 1 per cent. of calcium chloride (cryst.) had been added. After incubation for 15 minutes at 50°C these mixtures were thrown into water to ascertain if clotting had taken place.

TABLE VII.

Date of experiment	Dilutions of trypsin broth			
	1 in 50	1 in 100	1 in 1-0	1 in 2-0.
April 8th ...	Clot	Clot	Clot	Not done.
15th ...			Loose clot	No clot
25th ...				
May 25th ...				
July 1st ...			No clot	

Another series of experiments was made with the trypsin broth made up on April 8th to determine roughly whether it would retain its power to prevent the clotting of blood. A volume of the broth was mixed with varying quantities of blood and the formation or non formation of a clot noted.

TABLE VIII.

Date of experiment	2 vols. of broth 1 vol. of blood	1 vol. of broth 1 vol. of blood
April 8th ...	No clot	No clot
15th ...		
May 16th ...		
25th ...		
July 1st ...		

From these experiments it is seen that for at least seven weeks the broth may be kept at room temperature without loss of its tryptic power or of its power to prevent the clotting of blood but that after that period its deterioration becomes more evident.

Conclusions.—The authors' experiments have confirmed the findings of Wright and his fellow workers, which showed that when, by mixture with trypsin, the antitryptic power of blood is neutralised, the blood loses its power of clotting and also its antibacterial properties. These are precisely the changes which it is desirable to bring about when attempting to cultivate pathogenic micro-organisms from the circulating blood. A series of blood cultures performed in duplicate with trypsin broth and simple broth has shown that the employment of trypsin in that procedure is clearly advantageous—the organisms having been in some cases recovered only in the trypsin tubes, while in the other cases they were recovered earlier and more frequently in these than in the control tubes. It is probable that this method favours the cultivation of any microbe that may be present in the blood, and not especially one particular organism or group of organisms, as is the case with bile media, staphylococci, streptococci, paratyphoid bacilli and in one experiment not quoted, anthrax bacilli, were readily isolated from blood by the use of trypsin broth.

In order to be sure of neutralising the antitryptic power of the inoculated blood it is recommended to employ broth containing not less than 5 per cent. of trypsin solution (compound solution of trypsin, Allen and Hanburys) and to add not more than 1 c.c. of blood to each 5 c.c. tube of such a broth. When a supply of broth is not at hand or the blood has to be sent by post to a laboratory, undiluted trypsin solution may conveniently be mixed with the blood specimen immediately on its withdrawal from the vein, say in the proportion of 1 of trypsin to 4 of blood. Subsequently this unclotted blood should be planted into broth tubes for incubation—or where this cannot be done the blood may be incubated without dilution and the growth of organisms sought for in the plasma.

TREATMENT OF CARRIERS OF AMOEBIC DYSENTERY

NOTE ON THE USE OF THE DOUBLE IODIDE OF EMETINE AND BISMUTH.

By H. H. DALE, M.D., F.R.S.

(From the Department of Biochemistry and Pharmacology Medical Research Committee)

THE treatment of entamoebiasis in this country during the past year has been largely concerned with the problem of freeing the chronic carriers from their infection. Experience in Egypt in dealing with patients who continue to pass cysts after the dysentery has completely cleared up seems to have led to the conclusion that a full course of 10 or 12 grains of emetine hydrochloride, given hypodermically, will practically always eradicate the infection. The experience in this country, to judge from hospital records which I have had the privilege of seeing, does not altogether tally with this, for there seems to have been a not inconsiderable proportion of cases in which such a course of emetine has led only to a temporary absence of cysts from the faeces followed by an early recurrence. These cases, relapsing into cyst-passing again and again after successive courses of emetine have presented a difficult problem to the medical officers in charge of them. Their frequent occurrence among the cases treated in England was to be expected for these consisted largely of cases which had undergone relapse into chronic carrying, after apparently successful treatment of their acute infection with emetine, others had probably never been freed by repeated dosage with emetine before their return to this country, while others again, were apparently contact carriers with no history of previous dysentery or treatment. It was clearly a matter of importance that these men should be freed from the danger to themselves and to others entailed by the persistent focus of infection.

The pathology of the chronic carrier of *Entamoeba histolytica* seems to be still imperfect in that it has not been definitely ascertained whether the cyst-producing *Entamoeba* are living freely in the intestinal contents, like *Entamoeba coli* or are localised in a partly healed pocket or sinus. The occurrence of liver abscess without acute dysentery seems to favour the latter supposition. In either case the relative failure of hypodermic treatment with emetine in

this condition could be explained by the entamoeba being more or less completely shut off from the circulation and tissue fluids of the patient. The alleged superior efficacy in these cases of the older treatment with ipecacuanha by the mouth is in line with such a conception. By these considerations I was led to suggest a trial, in cases refractory to hypodermic emetine, of oral administration of this alkaloid in a form which gave promise of combining the advantages of the ipecacuanha treatment with freedom from its notorious difficulties and drawbacks. The results have been so far promising that it seems worth while, in the interests of a wider trial, to make mention of them at their present stage of incompleteness.

The compound which has been used is a double iodide of emetine and bismuth which was described last year by Du Mez, who suggested it as suitable for oral administration of emetine. It has the useful property, from this point of view, of being practically insoluble in dilute acids, but soluble with comparative ease in weak alkali. It might be expected therefore to pass the stomach unaltered, and then, being dissolved in the alkaline juices of the duodenum, to undergo gradual decomposition as it passed along the bowel, with liberation of emetine and precipitation of bismuth sulphide. Du Mez obtained promising, but rather irregular, results on dogs to which he gave the compound. So far as I have been able to ascertain it has not hitherto been tried clinically.

My colleague, Dr Barger, prepared me a sample of this double iodide, and I tested it, in the first place, on cats. I found that large cats, weighing upwards of 3 kilogrammes, could take repeated doses of 40 milligrammes without vomiting, the only effect being some looseness of the bowel. 60 milligrammes (containing about 20 milligrammes of emetine) produced vomiting, but the fact that this occurred some 5 hours after the administration, while purgation occurred about 1½ hours after the drug had been given, indicated that the vomiting was not due to direct irritation of the stomach, but was secondary to liberation and absorption of emetine in the bowel, and therefore comparable to the vomiting which follows a large hypodermic dose. If treatment with these larger doses was continued, the symptoms of chronic emetine poisoning, which I have previously described, made their appearance, as with hypodermic administration.

Messrs Burroughs Wellcome and Co kindly placed at my disposal a quantity of the compound for preliminary clinical trial, and further quantities were made to the order of the Medical Research Committee. The first trial was made at the Graylingwell Military Hospital, Gloucester, by kind coöperation of Lieutenant-Colonel H. A. Kidd, R.A.M.C., of Major J. L. Maxwell, R.A.M.C., and the other medical officers in direct charge of the patients, and of Mr Geoffrey Paget and Mr W. O. Redman King, who made the protozoological examinations. Mr King has furnished me with a résumé of the results on ten patients, all of whom had repeatedly shown early recurrence of cyst-passing after courses of hypodermic emetine. Of these patients six have already been discharged as cured, having failed to show any histolytica cysts, with stringent daily examination of the faeces, during six weeks, as result of a full course of the double iodide by the mouth. Two of these cases have not much evidential value, since the double iodide treatment was started while cysts were still absent, as the immediate result of a hypodermic course. The other four are open to no such criticism. A seventh case relapsed after a full course of the double iodide but, after a second course has been free from cysts for four weeks, so that a permanent cure is probable. The eighth case has been unable to stand a full course owing to nausea, but cysts have been absent for some time, with administration on alternate days, so that the result is hopeful. There remain one case in which relapse has occurred after two full courses and one in which the treatment could not be continued owing to the vomiting and diarrhoea which it caused.

Bearing in mind the fact that the cure of these patients had been practically given up as hopeless with the ordinary hypodermic emetine treatment, and that the standard of cure demanded—six weeks absence of cysts with daily examination—was a very high one, the results must be considered promising. Trouble occurred in some cases from vomiting but this was overcome in most instances. Administration during or just after a full meal seems to have been

the best method for avoiding vomiting, probably owing to the acidity of the stomach contents at this time. Some patients who were reported as vomiting with the first doses seemed to acquire a tolerance subsequently. The fact that the vomiting is delayed probably means that most of the dose is in the intestine before it occurs, so that the comfort of the patient is affected more than the efficacy of the treatment. 30 to 36 grains, equivalent to about 10 to 12 grains of emetine hydrochloride, has been regarded as a full course, and the daily dose has varied from 2 to 4 grains, given in capsules. 3 grains, representing 1 grain of emetine hydrochloride, seems to be a good average daily dose, and 12 such doses may be given in succession, unless giddiness, depression, or diarrhoea become severe. The frequency of vomiting is in no way comparable to that seen with the ipecacuanha treatment, and there is no need, as a rule, to restrict diet, to keep the patient recumbent, or to adopt the precautionary measures which the ipecacuanha treatment entails. The daily dose suggested of 3 grains of double iodide is equivalent in emetine to some 60 grains of ipecacuanha.

Several other cases, privately treated, are still under observation, but the results, which Dr G. O. Low and others have kindly communicated to me, are similarly promising. A further trial is in progress at another military hospital through the kind interest of the commanding officer and of Mr O. O. Dobell, who is responsible in this instance for the protozoological findings. One fresh case of acute dysentery has been treated by Dr Low with daily doses of 3 grains of the double iodide, with results apparently as good as those of the hypodermic emetine treatment. If it be a fact that the residual infection, with healing ulceration, is more accessible to the emetine given by the mouth, it may be worth while to consider whether the later doses of the usual course of emetine, given in an acute case, would not with advantage be given as the double iodide. It seems possible that the risk of subsequent "cyst-carrying" might thus be diminished. The possibility of using the emetine-bismuthous-iodide prophylactically seems to me also well worthy of consideration. I believe that most men could take a grain or so every few days without any notable effect on health, comfort, or efficiency. I am having some tablets prepared, keratin coated, as an additional safeguard against vomiting, and will try them on some normal subjects in the first instance. Experience would have to show how small and infrequent a dose would give protection to those exposed to the chance of being infected. A drawback to the wide use of the compound as a wholesale prophylactic would, under present conditions, be the expense entailed. The ordinary emetine salts are expensive enough, and the extra trouble of making the double iodide will presumably make the latter, dose for dose, even more costly, though the difference should not be very large.

My best thanks are due to the gentlemen above mentioned, who have interested themselves in the trials recorded and to others who are giving their coöperation in those still in progress.

Dr T. G. Moorhead, F.R.C.P. Irel, Captain, R.A.M.C. (at present on foreign service), visiting physician to the Royal City of Dublin Hospital, has been elected professor of practice of medicine in the School of the Royal College of Surgeons in Ireland, in room of Sir John Moore, retired.

AN EXAMINATION FOR MATERNITY AND CHILD WELFARE WORKERS.—In order to assist local authorities in the selection of suitable child welfare workers the Royal Sanitary Institute have just established an examination in sequence with the present examination for health visitors but requiring a wider experience and a more developed knowledge of the subjects cognate to child welfare, including ante-natal conditions and the various laws and regulations relating thereto. The examination will be supplemental to the health visitors' examination the certificate for which is one of the qualifications named in the General Order of the Local Government Board (1903) relating to the office of health visitor and school nurse. It is proposed to hold the first examination in London on Dec. 8th and 9th. A syllabus has been issued and can be obtained from the Secretary of the Royal Sanitary Institute, 99, Buckingham Palace Road, London, S.W.

A NOTE ON THE NECESSITY FOR PROLONGED TREATMENT IN CASES OF INFANTILE PARALYSIS

BY FRANCIS HERNAMAN-JOHNSON, M.D. ABERD.,
CAPTAIN (TEMPORARY) R.A.M.C. CONSULTING RADIOLOGIST,
ALDRSHOT COMMAND ETC

MUCH of our treatment of the weakness and deformity which may result from an attack of poliomyelitis fails owing to lack of proper "following up." I am fortunately able to illustrate the good effects of perseverance by giving notes and illustrations of the present-day condition of a child whose case I reported in THE LANCET of June 24th, 1911 (p 1700). The following is a quotation from that part of my article which described what was found in that case:

"The patient, a girl aged 5 years suffered from infantile paralysis of the right lower limb. The attack had occurred at the age of 18 months. The child was wearing an appliance weighing 6 lb., the main feature of which was a heavy steel running up the leg from ankle to waist and secured round the latter by a metal band. The patient progressed by a curious hopping motion dragging the affected limb behind her with the foot everted almost to a right angle. The limb had shown no improvement for two years.

"On examination I found all the muscles below the knee to be completely paralysed, so that the condition known as 'flail ankle' obtained. The thigh and buttock muscles were small and weakly, but they responded fairly well to faradic stimulation. Partial subluxation of the knee joint was also present, partly due to the lack of tone in the biceps and quadriceps femoris, but chiefly depending on the complete failure of the gastrocnemius. The whole limb was shrunken, and showed $2\frac{1}{2}$ inches of relative shortening. It was, moreover, cold and clammy to the touch with a temperature 2°F below that of its fellow, a condition which I judged to be in part due to the weight and rigidity of its supporting apparatus (Fig 1 shows the diseased limb). As is frequently the case in such limbs, sensibility to pain and changes of temperature was greatly diminished, although tactile sensation remained unaffected. A careful electrical investigation led me to conclude that the leg muscles were probably hopeless, but I nevertheless made bold to tell the parents that I would enable the child to do without external irons and that she need wear no support of any kind above the middle of the thigh."

FIG 4

Right knee-joint. January 1911. Note rudimentary patella and backward curve of limb

Right knee-joint. June 1915. Note normal shape of limb.

A special boot was constructed (weighing only 2 lb.), in which light steel supports were concealed (Fig 2). Under treatment by electrical stimulation a very rapid increase in size and power occurred in the buttock and thigh muscles. At the end of two months—when the treatment was suspended—there was not, however, any sign of improvement below the knee.

The child has been seen twice yearly until recently and has had about a month's electrical treatment on each occasion. At the end of two years I was surprised to find that power was beginning to return in the calf muscles and the "relative shortening" had decreased from $2\frac{1}{2}$ to $1\frac{1}{2}$ inches. I took away some of the support from the knee, and a year later removed it all. Early in 1915, four years after the patient

FIG 1

FIG 2

FIG 3

FIG 1.—1911 Shows backward displacement of knee and atrophy of calf muscles

FIG 2.—1911 Specially devised boot, no external irons, weight 2 lb. Artificially padded calf

FIG 3.—1915. The curve of the leg has become normal, tone having been restored in the hamstring and calf muscles

was first examined, some amount of control on the ankle joint had been regained and the affected limb is now only one inch shorter than its fellow. The child now wears an ordinary boot with a little leather stiffening, and an internal raised sole.

Fig 3 is unfortunately not so good a photograph as Fig 1. It shows nevertheless that the curve of the leg has become normal—a result due to the restoration of tone in the hamstring and calf muscles.

Figs 4 and 5 demonstrate that *pari passu* with the visible improvement, the size and density of the bones have increased.

The above is an example of a case properly dealt with over a period of years. There is a converse to such a picture—I have seen cases apparently much less severe go completely to the bad for want of constant attention.

Any apparatus which may be necessary needs frequent modification. Support must not be abruptly withdrawn from a recovering muscle, or it will relapse. On the other hand, if more aid is given than is necessary, progress will be retarded. In a favourable case the relative shortening of a limb should grow less year by year and therefore any boot extension must be altered accordingly.

The above is the mechanical side of the question. The physiological aspect is equally important. As to prognosis, the case here illustrated shows that an unfavourable opinion

is not always borne out by subsequent events, even though based on careful investigations. In most cases the prognosis is inseparably bound up with the treatment. The effect of electrical stimulation on nerves and muscles which still retain some power of response is rapid and marked. A surprising difference may be brought about in six or eight weeks, and the general growth of the limb is accelerated for some months afterwards. So long, however, as the child is growing there is a chronic tendency for the affected limb to lag behind its fellow, and there is thus need in young children for a short course of treatment at least twice yearly.

The therapeutic lessons which have been learned in connexion with infantile paralysis are of special interest at the present time, as the rules to be followed are for the most part equally applicable in dealing with war injuries to nerves and muscles. The three following, at least, should always be kept in mind—

1 A muscle which is chronically overstretched cannot recover. It must be relaxed by means of a suitable splint. This principle was insisted on by Robert Jones many years ago, and its importance cannot be over emphasised.

2 When such a muscle responds moderately well to faradism—or, in more modern terms, to the small or medium capacities of the Lewis Jones instrument—its recovery will be greatly hastened (and in some cases even determined) by daily rhythmical electrical stimulation. The relaxed position must, however, be maintained throughout.

3 Exercise, whether voluntary or electrically provoked, must never be carried to the point of fatigue. The contraction of a muscle should be not less vigorous—with the same stimulus—at the end of a sitting than at its commencement. It is better that recovery should be delayed by over caution than that it should be made impossible by excess of zeal.

SIX CASES OF WOUNDS OF THE BUTTOCK WITH PERFORATION OF THE INTESTINE

By R B BLAIR, M B EDIN, F R O S EDIN,
CAPTAIN R.A.M.C.

THIS short series illustrates the grave results which may accompany wounds inflicted by rifle or shrapnel bullets or pieces of shell in the region of the buttocks. I have learnt by personal experience that these wounds frequently penetrate the peritoneal cavity and cause injury to the viscera, and that they should therefore be subjected to the most careful investigation. During the last four months six cases of buttock wounds have been admitted into a ward under my charge at a clearing station. Some of these on first examination were thought to be slight but subsequently proved to be of vital importance. If the wound is probed and the track does not appear to pass towards the peritoneal cavity one may be led to infer that the abdominal viscera have escaped injury. The first of these reported cases shows that this test may be fallacious, and that further investigation is necessary.

It is frequently far from easy to be certain that penetration of the abdominal cavity has occurred. The signs and symptoms of such a lesion may be self evident, or, on the other hand, so anomalous as to give rise to great uncertainty. In those cases easy of diagnosis the general appearance of the patient is typical. The abdominal facies, pallor, sunken eyes and anxious expression, the legs drawn up, and respirations rapid and thoracic in type present an unmistakable picture. The abdomen is rigid and tender, vomiting is present and the pulse is rapid and wiry.

Difficulties in diagnosis arise when such symptoms are slight in degree. The facial appearance may not assume an abdominal character, but generally a look of distress is present. Vomiting may be a delayed symptom although nausea is often complained of. Abdominal pain may be slight and only elicited on pressure. Rigidity of the abdominal wall may be absent and tenderness may be limited to one localised part. The character of the pulse is perhaps the most important sign—its rate is invariably

increased. It becomes small in volume, thready, and may be irregular.

The most important guides, then, are the pulse and facial appearance. As one famous consultant remarked on seeing one of these cases "Yes, he looks more ill than a buttock case should." If the wound be probed, the track may or may not pass in the direction of the abdominal cavity. In all cases of doubt it is necessary to enlarge the wound and explore it thoroughly.

The first of these cases is a striking illustration of many of the points to which I wish to draw attention.

CASE 1—Shell wound of left buttock. *History*—Wounded at 10 A.M. on April 18th, arrived at V— at 10 P.M. same day, when he had cocoa to drink and vomited soon afterwards. He reached the clearing station at 1.30 A.M. on April 19th. He walked into the ward, said he was slightly wounded, asked for some cocoa, and said he wanted to sleep. He slept well, had a breakfast of tea and bread and butter at 7.30 A.M., and was sick once at 9 A.M. At 1 P.M. he passed a small, loose, dark motion, and said he felt much better. He complained of some abdominal pain, which he referred to the concussion of the shell.

On examination the patient did not look seriously ill, he showed no pallor, but there was an expression of distress. The pulse was rapid (110 to 120) and small in volume. The abdomen moved well on respiration, and rigidity was not present. There was slight tenderness on palpation over the brim of the pelvis on the right side, percussion gave a resonant note. The entrance wound, 1 inch above the left tuber ischii, had an inward and slightly upward direction towards the natal cleft. Vomited matter, dark brown in colour, not stercoraceous, and small in quantity. When the patient was first seen by Colonel H. M. Rigby he was standing upright, quite unconscious of his serious condition.

Operation at 4 p.m., April 19th—The buttock wound was laid open and the track was found to pass towards the coccyx, which was fractured. On this discovery it was decided to explore the abdomen. This was done by a median incision between the umbilicus and the pubes. On opening the peritoneal cavity no free blood was found. There was evidence of peritonitis in widespread patches of lymph along the lower coils of the small bowel. The lowest portion of the ileum was found adherent in the right iliac fossa, where free fluid like small bowel content was present. Free fluid was also present in the pelvis. An oblique tear 1 inch in length was found in the wall of the bowel about 18 inches from the ileo-caecal junction. Just inside the intestinal lesion there was a ragged piece of shrapnel about the size of the terminal phalanx of the thumb, within the lumen of the bowel. It was thought necessary to resect the damaged portion, and about 2 inches were removed. An end-to-end anastomosis was done with sutures of linen thread. The free fluid was mopped up with dry gauze, no other lesion was found. A rubber drain was introduced into the pouch of Douglas and the abdominal wall closed in layers with catgut. During the operation the patient had two pints of saline given subcutaneously.

Recovery was uninterrupted. The drain was removed on the fourth day, and secondary sutures were introduced into the buttock wound on the fifth day. The bowels were moved on the fourth day. On the tenth day after the operation the patient was evacuated to the base.

There are many points of interest in this case, but the most striking was the almost complete absence of symptoms indicating a severe abdominal injury. The patient was able to walk into the ward 13½ hours after being wounded, and was able to stand up 15 hours later. He had delayed vomiting in 12 hours after he received his wound although he had had fluids to drink. The severity of the lesion was obscured by the absence of definite physical signs, the extraordinarily good condition of the patient and the misleading direction of the track of the missile.

The following are brief notes of the five remaining cases, to which slight reference has been made.

CASE 2—Shell wound of right buttock. Wounded 10 A.M. Dec 19th, 1915. Admitted 8 A.M., Dec 20th. Entry wound situated 2 inches below and behind the anterior superior spine on the right side. No wound of exit. Vomiting took place on the evening of the 19th and once again after admission. No complaint of abdominal pain but tenderness was present in the right iliac fossa on palpation. Pulse rate 108.

Operation—Laparotomy, right rectus. A small quantity of blood was present in the abdominal cavity. A perforation was found in the right wall of the caecum and sutured with linen thread. Pelvic drain. *Result*—Died at 3 P.M. on Dec 21st. Extensive gas gangrene was found in the wall of the caecum and surrounding tissues.

Remarks—The patient did not look like an abdominal case. The pulse rate was increased and there was tenderness in

the right iliac fossa, but it was only after exploration of the wound that it was decided to open the abdomen

CASE 3 Shrapnel wounds of buttocks. Wounded at 10 A.M., Feb 13th, 1916. Admitted at 8 A.M., Feb 15th. Entrance wounds one in each buttock. No wounds of exit. Patient in bad condition. Repeated vomiting of dark brown serous raceous fluid. Pulse 130, thready.

Operation—Median laparotomy. A small quantity of free blood was found in the peritoneal cavity. Two perforations were found in the upper part of the ileum, with a tear in the mesentery. Four inches of gut were resected, and an end-to-end anastomosis was made. One perforation in the rectum was sutured. Pelvic drain. **Result**—Died four hours later.

Remarks—The signs and symptoms of a severe abdominal lesion were obvious. The patient had to remain in a "dug out" for nearly 48 hours on account of shell fire before being brought to hospital.

CASE 4—Gunshot wound of left buttock. Wounded 4 A.M., March 27th, 1916. Admitted 6 P.M. on same day. Entry wound 2 inch below the natal fold in the middle line of the posterior surface of the left thigh. No exit wound. Abdominal pain was felt one hour after the wound was received. He felt sick after admission, and vomited once before the operation. On palpation tenderness was present in the left iliac fossa. Pulse 80 of good quality.

Operation 10 P.M.—Laparotomy, left rectus. The peritoneal cavity contained a considerable quantity of free blood. Two small perforations were found in an upper loop of the ileum, and were sutured with linen thread. No other lesions were found. The bullet was not found. Suprapubic drain inserted. **Result**—Good recovery.

Remarks—The general condition and pulse were good. The history of abdominal pain after the wound was received was definite. The wound of entrance was below the buttock, but when shot the patient was in a stooping attitude.

CASE 5—Shrapnel wound of left buttock. Wounded 4 P.M., March 27th, 1916. Admitted 6 A.M., March 28th. Wound of entry in the left buttock. No exit wound. Abdominal pain and rigidity were present, vomiting took place on the evening of March 27th, and was repeated during the night. Pulse 120, feeble.

Operation—A catheter passed produced bright blood. The wound in the buttock was explored, and found to have fractured the coccyx. Median laparotomy. Multiple wounds were found in the small gut, and a tear 2 inches in length was found in the superior wall of the bladder. A double resection of 18 inches and 4 inches, with end-to-end anastomosis was done, three other perforations were sutured, and the tear in the wall of the bladder was closed by suture. A fragment of shrapnel was found lying in a fold of mesentery. Pelvic drain. **Result**—Died on completion of the operation.

Remarks—The condition of this case was desperate, he looked pinched and collapsed and the pulse was of very poor quality.

CASE 6—Shell wound of left buttock. Wounded 12 P.M., April 6th, 1916. Admitted 6 A.M., April 7th. Wound of entry in the left buttock, no exit wound. Tenderness on palpation was present in the right iliac fossa and the right lumbar region. The patient vomited twice after admission and during the night. Pulse 120.

Operation—Median laparotomy. A quantity of foul smelling fluid was present in the peritoneal cavity, but no blood. Peritonitis was generalised. Two perforations were found in the ileum, 12 inches from the ileo-caecal junction, they were sutured with linen thread. No fragment of metal was found. A pelvic drain was inserted. **Result**—A faecal fistula developed on the fourth day after the operation. The patient was evacuated to the base on the eleventh day after the operation. The discharge was then less, the pulse was 96, temperature 99.8° F., and the general condition was good.

Remarks—The patient looked ill, the pulse was rapid, there was vomiting, and the direction of the wound was towards the abdomen.

I wish to express my indebtedness to Lieutenant-Colonel J. W. Langstaff for his kind permission to publish these cases.

Sir Robert Woods, ex President, Royal College of Surgeons in Ireland, has been appointed honorary professor of larvæology in the University of Dublin.

DONATIONS AND BEQUESTS—The Chelsea Hospital for Women has received from the Public Trustee a grant of £1600 from the Geldart Estate, £50 from the Goldsmiths' Company and £250 from the Rev. Percival Laurence towards the cost of the rebuilding of the hospital. An anonymous gift of £10,000 3s. per cent. War Loan has been received by the governors of the Sheffield Royal Hospital. By will the late Rev. George Birkett Latreille Brownswood Park, Finsbury Park bequeathed 1000 guineas to the Great Northern Hospital Holloway for the endowment of a George and Philis Bed.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

A CASE OF DOUBLE CERVICAL RIB

BY HAROLD F. RENTON, M.D., B.S. LOND., M.R.C.S., L.R.C.P. LOND.

CASES of cervical rib are by no means uncommon, but the history of a case that came recently under my notice would seem to make it of sufficient interest to justify its publication.

The patient, a man aged 42, had been under treatment for a considerable period for what he called dyspepsia. This consisted of pain which passed in a girdle fashion along the left ribs from the axilla towards the breast and backwards towards the scapula. The pain had no relation to food, however, and nothing gave him relief. He came to see me on May 14th of this year complaining that he had injured his neck. He had been lifting a heavy sack of flour and had slipped in some manner, so throwing the whole weight of the sack against the side of his neck. Since the accident he had been troubled with persistent pain on the left side of the neck and a dull, aching pain down the left arm. The pain in the arm followed the inner aspect of the limb and passed downwards to the third and fourth fingers and the inner side of the ring finger. There was, moreover, a feeling of numbness on the inner and back aspect of the upper arm. The patient complained that his three inner fingers seemed to be asleep, and that the pain in the arm was worse when the limb was allowed to hang loose, vertically downwards, and when he rested his head on his pillow at night.

Examination—There was no superficial bruising or discoloration. The muscles of the left side of the neck appeared to be very highly developed, more so than those of the right, which was strange considering that the patient

Radiogram taken from behind showing cervical ribs. A, left; B, right. The first and second dorsal ribs on each side are marked I. and II.

was a right-handed man, and there was a large swelling completely filling the left supraclavicular fossa. The swelling was hard and immovable, and pressure upon it caused acute pain. The subclavian artery could be felt passing outwards across its surface and was proved to have no connexion with it. The movement of the arm was free in all directions, and the patient only complained of pain when the limb was pulled vertically downwards. There was no anaesthesia of the arm, though sensation along its inner aspect as far as the fingers was somewhat impaired. The power in the left hand was good. There was no delay in the radial pulse as compared with the right side, and the hand was warm and of good colour, proving that there was no interference with the circulation. A diagnosis of left cervical rib was made. The patient was subjected to X-ray examination and the diagnosis was confirmed. Moreover, the presence of a small cervical rib upon the right side was revealed.

The photograph of which the accompanying illustration is a reproduction was taken in the following manner. The patient was placed upon his back upon a couch the head being allowed to hang just over the edge. This position served to separate the ribs and throw the lower jaw away from the region of the neck. The plate was placed behind the patient, the exposure allowed being 45 seconds. A

mammoth tube was employed, the "rays" passing vertically from a distance of 20 inches

The interest of the case would seem to be centred in the following points 1 The absence of symptoms, with the exception of the girdle pain, until the day of his accident In a young individual symptoms are rare at first, but when the sufferer has reached the age of the patient under discussion pressure symptoms are commonly present 2 The possibility that the accident had resulted in partial dislocation of the cervical rib, so inducing an acute onset of the typical symptoms 3 The great length of the cervical rib as shown in the X ray photograph 4 The explanation of the distribution of the pain

The pain down the inner side of the arm and affecting the inner fingers, as described above, was due to pressure upon the lower nerve trunk of the brachial plexus, resulting in sensory disturbance in the areas of skin supplied by the lesser internal cutaneous, internal cutaneous, and ulnar nerves The pain spreading in girdle fashion round the left ribs, which had been attributed to dyspepsia was probably reflex in origin, passing from the lesser internal cutaneous to the second intercostal nerve by way of the intercosto-humeral nerve which communicates with both

Oldham

A CASE OF OMENTAL FIBROMA

By E MANSEL SYMPSON, M D CANTAB, M R C S,
HONORARY SURGEON LINCOLN COUNTY HOSPITAL, LIEUTENANT COLONEL,
R A M C (T F) 4TH NORTHERN GENERAL HOSPITAL.

As peritoneal or omental fibromata are not very common it seems worth while placing the following on record

The patient, a married woman aged 37, was sent to me by Mr H H Ballachey, of Heckington, and admitted to the Lincoln County Hospital on May 9th suffering from an abdominal tumour She had had four children (three now living), one miscarriage 11 years ago the last child having been born seven years ago For eight years past she had noticed a "lump" growing in the left iliac fossa In September, 1915, this suddenly increased in size and became more centrally placed in the abdomen She complained of a good deal of abdominal pain (rather vague, dragging and referred to the epigastrium), and had had several attacks of vomiting Neither of these had borne any time relation to food The bowels generally were rather confined, and there had been some loss of weight She was anæmic and emaciated A plainly visible tumour occupied the entire umbilical, lower part of the epigastric and the major part of the left iliac fossa, moving with respiration It was very freely movable within the abdomen, attended with little discomfort to the patient It appeared to consist of a hard central portion, surrounded by a very soft but not exactly fluid peripheral part No pulsation was felt in the tumour The percussion note over the whole tumour was dull, otherwise the abdomen was normal Examination per vaginam Uterus normal in size, freely movable irrespective of the tumour Right ovary felt to be normal, left one could not be felt owing to the left fornix being occupied by the new growth As she was menstruating operation was delayed until May 15th A central incision about 6 inches long was made with its centre at the umbilicus The tumour presented itself at the wound directly the peritoneal cavity was opened It was possible to lift the tumour bodily out of the abdominal cavity, when it was found to be attached to the great omentum, which covered it entirely, by a flattened pedicle about 1 inch wide and several inches in length (joined on to a piece of small intestine), which carried two large arteries and two large veins which were continuous with the vessels of the great omentum This pedicle was ligatured, cut, and the tumour, which weighed 6½ lb, removed Beyond a clot of coagulated lymph in the pouch of Douglas and some engorgement of the omental vessels, the contents of the abdominal cavity seemed quite healthy, the uterus, ovaries, and uterine ligaments certainly were so The wound was closed, the peritoneum being sewn up with continuous catgut sutures and the skin wound with intermittent silkworm gut sutures The operation lasted 25 minutes Open ether was administered as the anæsthetic The patient made a speedy convalescence and was discharged one month after the operation, having gained 1 st in weight

The tumour was sharply divided, apparently into two entirely separate zones The outer cortical one had obviously undergone complete colloidal degeneration, and was soft and gelatinous in consistence The inner part or medulla of the tumour was hard, white in colour, and friable in parts The entire tumour was distinctly non-vascular, except for the vessels at and in the pedicle The Clinical Research Association reported on it microscopically

as follows "The tumour is composed of a connective tissue stroma with cell elements varying in different parts. The general structure is that of a fibroma, undergoing degenerative changes, with large areas of necrosis. There is no evidence that it is a malignant growth"

For the notes and for kind and skilful assistance at the operation I have much pleasure in thanking our resident medical officer, Mr W F Stiell

Lincoln

CASE OF FOUR DAYS' STRANGULATED HERNIA IN A CHILD 15 DAYS OLD, RECOVERY

By IDA M GUILLAUME, L R C P & S EDIN,
L R F P S GLASG,
SENIOR HOUSE SURGEON OLAYTON HOSPITAL, WAKEFIELD

A male child aged 15 days, very emaciated and apparently dying, was admitted to Olayton Hospital under the care of Captain J W Walker, R A M C (T), senior honorary surgeon

The history obtained was that for four days the child had vomited everything given, had seemed in great pain, and had had no motion for that period in spite of aperients On admission, the vomiting was frequent and fecal, and a left irreducible inguinal hernia was found Captain Walker operated immediately on the child. Under chloroform the sac, which was tightly strangulated, was found to contain large bowel in just good enough condition to be returned to the abdomen The testicle was found to be gangrenous, probably from pressure, and was removed The child made an uninterrupted recovery The interesting points of the case are The extreme youth of the patient, his moribund condition on admission, the length of time during which, judging by the symptoms the hernia had been strangulated and the fact that the vomiting was fecal, and the necessary removal of the testicle In the circumstances the recovery was very satisfactory

I am indebted to Captain Walker for permission to publish the case

Wakefield

Reviews and Notices of Books.

Physiological Chemistry A Text book and Manual for Students

By ALBERT P MATHEWS, Ph D, Professor of Physiological Chemistry the University of Chicago Illustrated
London Baillière, Tindall, and Cox. 1916 Pp x-1040
Price 21s net

THE author expresses the view that his book may raise in the minds of those who read it more questions than it answers The remark is not inappropriate as biochemistry is so recent a subject that to few of its fundamental questions can we give an answer A feature of the work is the citation of definite experiments rather than conclusions only, so that the reader may judge the evidence for himself

The text of this well planned volume is divided into three parts Part I deals with the chemistry of "Protoplasm and the Cell" (pp 1-265), Part II with the "Mammalian Body Considered as a Machine Its Growth, Maintenance Energy Transformation and Waste Substances" (pp 266-847) and Part III with "Practical Work and Methods" (pp 848-1012) which gives an account of the course in physiological chemistry at the University of Chicago The scheme and details are much on the lines practised in the chemical departments of physiological laboratories in this country At the end of each chapter will be found a short list of papers—most of them of recent date—bearing on the subject dealt with in that chapter A commendable feature is the introduction of the derivation of the scientific words used and their meanings In Part I the chemistry of the carbohydrates, fats and proteins, and the physical chemistry of the cell are longer than is usual Under the term "Lipins" are included fats, oils waxes, phosphatides and sterols—a heterogeneous group both physiologically and chemically—the group designated 'Lipoids' in this country Part II opens with a short chapter on animal heat, in which ample justice is done to Lavoisier and other

early French observers. In the references we miss the well known work of Charles Richet, "La Chaleur Animale" which contains a large number of original observations as well as matters of historical interest. The account of the raw materials of food is short but perhaps sufficient. Three chapters are given to digestion and a short one to absorption. In the account of the blood—the circulating tissue—the author adopts the view of Wooldridge, and considers the whole blood, the more liquid portions together with the corpuscles, both red and white, the platelets and the cells lining the blood vessels as consisting of a great mass of living protoplasm. Indeed, the author goes so far as to state that we shall probably not go far wrong if we consider the blood plasma as a very dilute protoplasm. The processes which occur in it are probably the mirror of the processes which occur in all forms of living matter. In the chapter on the brain and nervous system the author eulogises the work of Thudichum, 'a man of extraordinary care, accuracy, insight, and industry, whose abilities were much underrated during his life. There is now, however, no question that he was far in advance of all others in this difficult field.' The absence of reserve carbohydrate food in the brain and the entire absence of neutral fat are noted as striking and interesting facts, while the medullary sheath of the nerves may be a reserve food and a nutritive material. In his speculations regarding memory the author suggests "memory hormones." Indeed, "in the spontaneous oxidation of linoleic acid phenomena closely paralleling memory and learning occur." Muscle and connective tissues are dealt with on the usual lines and a somewhat full account is given of the cryptorrhetic tissues—i.e., endocrine glands. A chapter is given to the excretions and one to metabolism of the body considered as a whole one to protein metabolism, and another to metabolism under various conditions, respiration and vitamins.

The book as a whole is excellent in matter and agreeably written, with here and there quaint suggestions and comparisons which help to illuminate the text and suggest new ideas to the reader. Many facts not recorded in Parts I and II will be found in Part III, so that in this way an overlapping is avoided. The work should prove most useful to all interested in physiological chemistry.

JOURNALS

The Philippine Journal of Science Vol. X. Section B. *Tropical Medicine* No. 6.—The opening paper of this number deals with certain observations made on the treatment of the skin lesions of leprosy with basic fuchsin by Dr. Oswald E. Denney, of the Cullion leper colony, Philippine Islands. He treated 132 cases with various external leprotic lesions including ulcers, gangrene, &c. by means of cotton pledgets soaked in 1 in 1000 aqueous solution of basic fuchsin packed into the lesions and kept in place by gauze bandages. A stronger solution—e.g. 1 in 500—caused a burning sensation and its use was not continued. The result of the treatment was that of the 132 cases the skin lesions were healed in 67, improved in 46, no improvement was shown in 14 and 5 died. In this series of cases basic fuchsin as an antiseptic proved most satisfactory, as an epithelial and granulation tissue stimulant it brought about repair in many instances which had resisted several other forms of medication. Apart from the slight burning sensation caused by the use of the stronger solutions neither discomfort nor toxic effects were noted in any case. In consequence of these observations we learn that several hundreds of lepers are now being treated with this remedy daily in the Philippines and with equally good results. This paper is illustrated by three plates.—Another contribution deals also with the subject of leprosy and is furnished by Dr. John A. Johnston of the Bacteriological Laboratory, Bureau of Science, Manila. The writer gives a general account of the history, etiology and prevention of the disease. He believes that leprosy was imported from Japan to the Philippines. The first leper hospital in Manila was established by the Franciscan Order in 1633. At the present time about 3000 Filipino lepers are interned on the island of Cullion. The author defines leprosy as an extremely chronic, practically incurable disease.—Dr. Fernán de Calderón writes on tropical obstetrical problems and gives some account of the many superstitions prevalent among the native Filipino population concerning pregnancy

and childbirth. When an obstetrical department was established at Manila in 1907 great difficulty was experienced in inducing mothers to come to the institution to be confined, most of them preferring to be delivered in their own dirty and insanitary homes. But gradually the people's confidence has been obtained, and from 1907 to 1914 some 3707 women have been attended in childbirth by the medical officers of the department, with a total of 157 deaths, or 4 per cent. There were 171 abortions. A number of the deaths occurred in the earlier years when many of the cases sent in had been unsuccessfully treated by native methods and arrived at the institution suffering from injuries already inflicted or in a state of exhaustion which gravely affected their chances of recovery.—Dr. J. S. Coulter contributes a study of the pathology of the gall-bladder and biliary passages in cholera. This observer during 1913 and 1914 examined post mortem 305 cases, 13 of which showed signs of inflammation of the gall-bladder, or about 4 per cent. This percentage is practically the same as that recorded by Major E. D. W. Greig, I.M.S., in his reports upon the subject. This number completes Volume X. of the *Journal* and accordingly a full index is appended.

The Indian Journal of Medical Research, Vol. III. No. 4.—This number contains 15 articles all of scientific or practical value. The first is by Captain J. Morison, I.M.S., on the Dose of Alum for the Clarification of Water by Precipitation and gives the results of some experiments with the Poona water supply, which, it appears, is liable to considerable pollution after every rainfall in the catchment area. The best dose of alum for the perfect clarification of a soft water is obtained, it seems by adding half the equivalent weight of alum necessary to react completely with the alkalinity calculated as calcium carbonate. For a hard water the same rule holds but an equally good clarification can be obtained by the use of a smaller dose and a mechanical filter. Captain Morison has devised a method of making a colorimetric estimation of, and hence a check upon, the dose of alum actually used. In this method he employs a solution of logwood, and with doses in excess or in defect he gets a gradation of shades of colour. The clarification obtained by adding the optimum dose of alum is not affected by the turbidity of the water within the wide limits of turbidity found in the Poona water supply. The paper is illustrated by a coloured plate.—Captain Morison in conjunction with Captain W. D. Keyworth, I.M.S. also contributes an article on Flies and their Relation to Epidemic Diarrhoea in Poona, and in it the conclusion is arrived at that flies, whatever may happen elsewhere, in spite of their number do not contribute appreciably, if at all to the mortality in the native city of Poona or to the annual epidemic of gastro-intestinal disease in the Poona cantonment.—Mr. R. S. Cree Brown, professor of engineering in the Poona College of Science, describes an apparatus for the purification of water for troops illustrated by diagrams, and to this Captain Morison adds a note.—In further continuation of his special studies of cholera, to which he has already devoted so much attention Major E. D. W. Greig, I.M.S., gives an account of some serological investigations and classification of cholera like vibrios isolated from the water of tanks, wells, ponds, and river at Calcutta.—Major S. R. Christophers, I.M.S. and Sub-Assistant Surgeon Rai Sahib Khazan Chand (of the Central Malabar Bureau, Kasauli) describe a tree-hole breeding anopheles from Southern India, *A. (coelodiazensis) culiciformis* Cogill, with an illustrative plate.—Major W. F. Harvey, I.M.S., director of the Central Research Institute, Kasauli, writes on the Measurement of the Degree of Agglutination of Bacteria. He is of opinion that the degree of agglutination produced by a serum can be satisfactorily measured by using a suspension which has been standardised by weighing the bacterial substance and suspending it in unit volume of fluid. The degree of agglutination is most delicately determined by using time as a measure instead of dilution of serum. The test is greatly refined by using a heavy suspension with distilled water as menstruum and diluting and separation of the stages of occurrence of agglutination. The modified test is said to be rapid, simple, delicate and definite.—Major Harvey also contributes two other articles—namely a note on vaccination and some remarks on the investigation of an epidemic.—In a highly technical paper Major A. McKendrick, I.M.S. director of the Pasteur Institute of India, discusses the Applications of the Kinetic Theory of Gases to Vital Phenomena. This paper, which is

illustrated by diagrams, was read before the Physical Section of the Indian Science Congress at Lucknow—A contribution to the study of kala azar is furnished by Lieutenant-Colonel J. W. Cornwall, I.M.S., in association with Military Assistant Surgeon H. M. La Frenais, illustrated by several plates. These experts found that *Leishmania flagellates* can survive in the bug for at least 29 days, and they suggest the possibility that a hitherto undescribed phase of the parasite of kala azar may occur in the bug's stomach. They found, however, little to support the view that this disease is transmitted directly by the bug to man, but the subject is being further investigated—Colonel Cornwall, in conjunction with Sub-Assistant Surgeon S. Ramasamy Aiyar, of the Pasteur Institute of Southern India, discusses the subject of Arnet's index in laboratory rabies—Dr. Vishnu T. Korke writes on a nosoma (*Nosoma pulicis*, N.S.) parasitic in the dog flea (*Ctenocephalus felis*), illustrated by a plate—A contribution to the study of hemoprotozoa in Portuguese India is supplied jointly by Captain Froilano de Mello, professor at the Medical College of Nova Goa, and Dr. L. J. Braz de Sa, assistant in the bacteriological laboratory at Nova Goa. This paper is illustrated by a coloured plate—A report is published from the Kitchener Indian Hospital at Brighton on Pyorrhea Alveolaris and Associated Conditions among Indians and Europeans. In it an interesting account is given of the inquiry carried out by a committee of five members, four of whom were officers of the Indian Medical Service, with whom was associated Mr. H. L. Dorrell, dental surgeon to the hospital—The last contribution is furnished by two civil assistant surgeons—namely, M. Kesava Pai, M.D., and S. Rama Krishnan, L.M.S.—on the Differentiation of Dysentery Bacilli by their Agglutination Reactions—This number completes the third volume of the *Journal*, and accordingly an index of authors and another of subjects is appended.

NATIONAL INSURANCE ACT

A Panel Practitioner and Service Outside his Area

A SUCCESSFUL claim for fees was made in the Liverpool county court recently in somewhat unusual circumstances. Mr. M. R. Maher sued the widow and administratrix of the late Mr. S. J. Bland for £13 3s. 6d., on account of medical attendance upon her in 1913. The services claimed for were rendered before the husband died, and the debt was disputed on the ground that as Mr. Maher was Mrs. Bland's panel doctor he could not charge for attending her. It was also denied that any special arrangement for his attendance, as alleged by him, had ever been made. The plaintiff's case, however, was that after he had been in attendance on Mrs. Bland it was found that a serious operation was necessary, and she was removed to a nursing home for that purpose, the proposal that she should go into a public hospital at Liverpool being rejected. In these circumstances Mr. Maher was specially requested by the husband to attend her at the nursing home, and he accordingly did so, three operations being performed on different dates. The nursing home was at Waterloo, at some distance from the plaintiff's residence and practice, and he was particularly told by the husband to spare no expense. This, as has been stated above, was denied by witnesses on behalf of the defendant. His honour Judge Thomas, however, held that it was unreasonable to suppose that Mr. Maher would undertake to attend Mrs. Bland at Waterloo unless he were to be paid for going so far from home. He considered that the plaintiff was entitled to charge for his visits to Waterloo but not for attendance before the patient went there, and that he was not entitled to charge attendance fees at Waterloo as well as fees for the operations. He gave judgment for the plaintiff for £9 0s. 6d. with costs.

Panel Practitioners and the Military Service Act in London

At a meeting of the Local Medical and Panel Committees for London held on July 18th a report was considered from the committee appointed to confer with the Insurance Committee on the position of panel practitioners under the provisions of the Military Service Act, 1916. The attention of the Committee had been specially directed to the list of practitioners liable to be selected for commissions in the Royal Army Medical Corps on August 7th. The majority of these

it was found, would be able to make satisfactory arrangements for their patients if it should become necessary for them to do so, but in other instances, reduced eventually to 36 names, considerable difficulty would be experienced. These 36 names, together with the reasons why they should be retained in civil practice, have accordingly been forwarded to the Commissioners, who will make the necessary representations to the military authorities. The chief point to which the Committee directed its attention was the difficulty, varying according to the district, of obtaining full time deputies or of securing the whole-hearted co-operation of non-panel practitioners in undertaking the obligations of panel practitioners called up for service. Special consideration should, the Committee thinks, be given to areas in which in normal times all or most of the practitioners are on the panel, these being as a rule densely populated districts. A substantial number of practitioners from such areas are already serving, and further depletion of the ranks of panel practitioners must seriously affect the efficiency of the medical service provided.

Panel Practitioners and the Report of the Royal Commission on Venereal Diseases

The report of the special subcommittee appointed to deal with the above report was also in the agenda of the recent meeting of the Local Medical and Panel Committees for London. Many of the points which engaged the subcommittee's consideration naturally affect other practitioners equally with those engaged in panel practice, and the importance of the subject dealt with claims the attention of all. The difficulties to which the report in question draws particular attention are those arising out of the Commission's recommendation (9) that institutional treatment should, as far as possible, be provided at general hospitals. It is feared that patients will select a hospital for treatment in preference to going to their own medical attendants or to private practitioners, in order to secure themselves from the observation of their friends. Recommendation (10) runs: "Treatment in any institution included in a local authority's scheme should be free to all. There should be no refusal to treat a patient who is unwilling to go to his own doctor." In this connexion it is pointed out in the subcommittee's report that two points will have to be weighed carefully. First, the ethical question of how far a practitioner, whether on the staff of an institution (and so not peculiarly interested) or not, should undertake the treatment of another practitioner's patient before such patient has given notice to his original attendant. Secondly, the question of how far the treatment of a patient in a hospital, and without payment, is to be justified when the patient can secure for himself adequate treatment from a private practitioner. Recommendation (12) again arises out of the desire that patients suffering from venereal diseases should be able to obtain treatment in hospitals, with the apparent implication that venereal diseases are to be placed upon a different basis from other illnesses. This recommendation runs: "Special arrangements such as evening clinics, should be made for the treatment of out-patients at hours convenient to the working classes." It is pointed out here that evening clinics at general hospitals cannot fail to be regarded with anxiety by private practitioners in the neighbourhood. These clinics, also, if open only to venereal cases will mark out as such those who seek treatment at them, and surreptitious attendance will be necessary on the part of patients who wish their friends not to know of their condition. If, on the other hand, evening clinics are opened to include all kinds of disease, the competition with practitioners in the neighbourhood will become even more severe and the abuse of hospital treatment more frequent. The report suggests that the chief value of special hospital clinics will be in the provision of opportunities for medical practitioners to bring or send difficult cases for consultative advice, and that in fixing the time there should be consideration for the convenience of the practitioner should he desire to attend.

FREE TRAINING TO BELGIAN DOCTORS.—We understand from the Dean of the University of Liverpool that instruction in tropical medicine is being offered free of charge to Belgian doctors in this country by the Liverpool School of Tropical Medicine.

THE MEDICAL TREATMENT OF CANCER

Revue Moderne de Médecine et de Chirurgie.

As a result of over ten years' research work on Cancer Dr Gaube du Gers produced a new Colloidal Copper Hydroxide which has given remarkable results in *arresting the progress of the disease*, loss of pain, and great improvement in the general condition of the patient. Locally, these results are manifested by a transformation of the lesions, leading to their cicatrization, in a greater or less period, to the diminution in their size, and finally to the disappearance of the diseased glands. Dr Gaube du Gers' Cuprase is employed in subcutaneous injections made *very slowly* in the gluteal region, with a needle of about 0.03 cm. at the rate of an ampoule every four days which should be continued in the same manner as long as necessary. These punctures are not generally painful and do not produce any local reaction. Cuprase is not toxic.

Dr OLERICI has published a résumé of over sixty clinical histories from various Italian doctors and concludes as follows: "To sum up, Cuprase has given positive results in about 94% of the cases in which it has been employed for a sufficiently long period, and some brilliant results in about 20% of these cases. Henceforth, it may be affirmed that among the internal remedies for cancer Cuprase is the one which has produced the most successful results and can under certain circumstances compete with surgical methods, even so far as the rapidity of their results are concerned." *It should be remarked that all, or nearly all, the observations refer to inoperable cases in which the prognosis was unfavourable at an early date.* Dr MANCINI PAUL, physician to the hospitals at Rome, says: "In the present state of anti-cancerous chemotherapy, there is no product, both from the theoretical point of view and from that of positive results, which is superior to Cuprase."

Extract from Proceedings of the Royal Society of Medicine, February, 1913.—

Dr GEORGE HERSCHELL During the last year a considerable amount of work has been done in the treatment of cancer by colloid copper, and I do not think it should be passed over in this discussion without careful consideration. I am able to find histories of fifty three cases reported in the French Medical Press, in which a cure was claimed in fourteen cases (26.7%) and improvement in thirty six cases (57.9%). In three cases no good appears to have resulted. Making every reservation for unreported cases in which success was not obtained, I think that we must admit that some good results have followed the use of colloid copper in cancer unless we are prepared to assert that all the medical men who have reported these cases are engaged in a gigantic conspiracy for their own ends to delude the medical public of all nations. In some of the reported cases the diagnosis is, I admit, open to question. For instance, one case in which a cure followed the treatment, was obviously one of duodenal ulcer and not cancer of the stomach. But in others, in which equally good results have been reported, the diagnosis was confirmed by men of the very highest standing.

There are two kinds of colloid copper. The electrically prepared colloid which is manufactured by passing an electric arc through copper plates immersed in water and the chemical colloid which results from the slow reduction of copper in the presence of albumosic acid. Theoretically, the electric colloid should prove most efficacious as the particles of copper are reduced to the finest state of subdivision. Clinically however the chemical colloid appears to give the best results. In the following cases chemically prepared colloid was used. Experimentally, it has been proved: (1) That particles of colloid copper can be demonstrated in the granulations of cancerous growths after two or three injections of the colloid, and clinically (2) There is invariably great relief from pain, (3) Appetite and strength return and the patient puts on flesh, (4) There is in many cases a diminution in the size of the tumour, (5) The injections are absolutely non-toxic, although in many cases an inflammatory reaction is manifested in the cancerous growths.

As regards my own personal experience in the use of this method of treatment in addition to my own cases, I have had an opportunity of observing the effects in the practice of some of my medical friends, and in nearly all cases the progress of the disease appeared to be arrested.

OBSERVATIONS.

SUPERFICIAL CANCERS

- Skin, Lips, Mouth, Pharynx, Tonsils, Tongue
- Rodent Epithelioma of the External Canthus of the Left Eye with Destruction of the Eyelid Dr Arnaldo Taparelli, Assistant at the Royal Clinic for Skin Diseases, Modena
- Cancer of the Lachrymal Sac, Relapsed Dr Nicolo Lavagrinese, Osternino (Bari)
- Ulcerous Canceroid of the Leg Dr Raymond Laroche, licencié ès lettres, ex House Surgeon of the Hôpital de Dijon, Châteaun Landon (Seine-et-Marne)
- Cancer of the Floor of the Mouth and Right Tonsil Dr Colliere, Saint Amans-des-Côtes (Aveyron)
- Inoperable Glandular Sarcoma of the Tonsil, successfully treated by Cuprase and X Rays Drs Wolze and Alexander Pagenstecher of Brunswick (in *Münchener Medizinische Wochenschrift*, No 19, May, 1913)
- Tonsillar Neoplasm treated by Cuprase Dr Caillebar, Sandemagnan (Gers)
- Epithelioma of the Larynx and Mouth Dr Constant Ferrand, Paris
- Inoperable Epithelioma of the Pharynx and Fances Drs Garbarini of Parma and A. Tomasini of Rocabrana
- Cancer of the Tongue and Fauces Dr Bonetti Giacomo, Physician at the Sanitary Department Nuvoletta Brescia

CANCERS OF THE DIGESTIVE TRACT

Stomach, Intestines, Rectum

- Cancer of the Stomach treated by Dr Gaube's Cuprase Dr B Caillebar, Sandemagnan (Gers)
- Cancer of the Stomach Dr Amselle, formerly House Surgeon, Hôpitaux de Nancy, Epemay
- Cancer of the Stomach, Disappearance of the Gastric Tumour Dr George Herschell, M D Lond, Professor Fellow, Royal Society of Medicine, Chief Physician, the London Hospitals (Extract from the *Proceedings of the Royal Society of Medicine*, London January, 1913)
- Cancer of the Stomach Dr George Herschell, M D Lond (see preceding paragraph)
- Cancer of the Stomach Dr George Herschell, M D Lond (see above)
- Cancer of the Stomach Dr George Herschell, M D Lond (see above)

OBSERVATIONS—(continued)

CANCERS OF THE BREAST

- Recurrence of Cancer of the Breast after Operation, Treatment by Cuprase, Cure Dr Chevassu Périgny, Orsennes (Indre)
- Cancer of the Breast Dr Haring, Toulouse
- Epithelioma of the Left Breast Dr Nicolo Lagravinese, Cisternino (Bari)
- Double Scirrhus of the Breasts and Neoplasm of the Ovary with Ascites Dr P Vignard, Surgeon of the Hôpital de Lyon, Hospice de la Charité
- Cancer of the Breast, Diffuse Cancerous Disease Dr Costanzo Visetti, Physician, Hospice Mauriziano, Aoste
- Cancer of the Right Breast Dr Dieudonné, Liège (Belgique)
- Epithelioma of the Breast Dr José Gimenez of Guillena, Province of Seville (Spain)
- Cancer of the Breast, Two Relapses Dr S of S
- Cancer of the Breast, Two Operations, Relapse Dr Marcelin, Favorney (Haute Saône)
- Cancer of the Left Breast with Ulceration, Tumour, Cure Dr Timmerman, Paris Plage.
- Ulcerated Cancer of the Breast Dr Usquin, Douzy (Nièvre).

CANCERS OF THE UTERUS

- Ulcerated Cancer of the Cervix Uteri Dr Coutouzis, Smyrna (Asia Minor)
- Cancer of the Uterus Dr Jacques Besson, Chalons sur Saône
- Cancer of the Uterus Dr Groc, Saint-Symphorien
- Cancer of the Cervix Uteri, Cure Dr Enrico Guicciardi, Modena
- Cancer of the Uterus Dr Antonio R Gomez, Los Angeles, California (U S A)
- Cancer of the Uterus Dr Antonio R Gomez, Los Angeles, California (U S A)
- Ulcerated Epithelioma of the Cervix with Infiltration of the Uterus, Cure Dr Giuseppe Cortese Nicolsia
- Cancer of the Prostate Extending to the Bladder, treated by Dr Gaube's Cuprase Dr Henri Maringer, formerly Assistant to the Clinic for Urinary Diseases at Hôpital Necker
- Cancer of the Upper Biliary Ducts with Billo-Septic Fever, treated by Cuprase, Cure Dr G Chevassu Périgny, Orsennes (Indre)

CONCLUSIONS

The action of Cuprase is manifested by local and general phenomena

A—LOCAL PHENOMENA

(a) The ulcers are cleansed, become roseate and pointed, lose their bad odour, dry up, are healed from the circumference towards the centre. The cicatrix is white, supple, and painless

(b) The affected glands cease to enlarge and remain in the same state or retrogress until they completely disappear

(c) The tumours become painful at first under the influence of the remedy (characteristic of specificity), this pain is special, characteristic, unusual, remarkable in nearly all the patients. Afterwards, either they no longer increase in size, and then present the characteristics of benign tumours, or else they begin to retrogress, retrogression of possibly the third the half, two-thirds, or even the whole. In the last condition nothing remains to show that the organism has ever been diseased

B—GENERAL PHENOMENA

The following facts may be considered as being practically established—

(a) The return of the appetite, which may be insatiable, and the steady increase in weight, often very great

(b) The return of the colour and strength, the capacity for life's occupations the patients 'obtain a new lease of life.'

(c) The disappearance of the pain. Cuprase exerts a powerful analgesic action and under its influence the violent pains, which had resisted the effect of large doses of morphine or which the morphine had only relieved in a very imperfect manner, have rapidly disappeared, never again to return

(d) Return of sleep. This as a consequence of the disappearance of the pain

12 *Hæmostatic action*. This action mostly rapid and manifesting itself from the first injection, even when the classical methods have failed

13 *Action upon the blood*. Under the influence of Cuprase the number of red corpuscles is greatly increased, as well as their richness in hæmoglobin

CUPRASE

CUPRASE is a colloidal copper hydroxide, which is obtained chemically, by the reduction of salts of copper in the presence of albumosic acid

The colloidal copper should be kept in yellow glass ampoules sheltered from the light, the ampoules which we use have a capacity of 5 c c, each ampoule contains 121 hundredths of a milligramme—viz., 0.00121 gm. of pure copper. The colloidal copper can be directly injected, it is not toxic, the injections are made subcutaneously or intramuscularly in the lumbar region or lower. They are painless, but on account of the viscosity of the liquid should be performed slowly. They are not generally followed by any reaction, either local or general, sometimes when a drop of blood appears on the skin after the needle is withdrawn, in the 24 hours following the injection a painless erythema followed by slight itching is observed above and around the puncture, this accident, which is insignificant may easily be avoided by puncturing with the needle only before injection, if no blood appears on the needle socket the injection may be proceeded with safely. The injections are renewed every four days at the commencement of the treatment, the intervals can afterwards be increased or continued in the same manner, according to the tolerance of the patient, or even doubled if the condition of the patient requires it, but not more than one ampoule should be injected in the same place

The curative action of the colloid would seem to be slower on the operable and recurrent cancers than on the inoperable. Nevertheless, the curative action of the colloid is as marked on the recurrent cancers, but is slower on account of the extent of the disease which is greater in surface and in depth. Every cancer left to itself ends in a rodent ulcer. Under the influence of the colloid this ulcer gradually shrinks from its circumference towards the centre in proportion as the cancerous tissue surrounding the ulcer disappears, the ulcer dries up in the centre, but it is not healed until the peri cancerous and cancerous tissue itself has disappeared. The secondary infections which so often accompany the cancerous ulcers are not affected, or very little so, by the colloid, but I have observed that from the commencement of the treatment of the ulcerated cancer by the colloid the cases of secondary infections became more and more rare

The intensity of the destructive action of the colloidal copper on non ulcerated cancer appears to be in direct proportion to the rapidity of its development—that is to say, the colloidal copper is more effective in its action upon cancers with rapid development than upon those of slow development or rather, acute cancers heal more quickly than chronic ones, if one may so express it

CUPRASE is put up in boxes containing 8 ampoules of 5 c c each

Science and the Drink Question

THE neglect of science by the State is one of the commonplaces of current thought. It is said, and in too many instances no doubt with perfect truth, that in this country the governing classes, or at all events our legislators and politicians, fail very generally to recognise the importance of science in modern life, and that they are unable or unwilling to appreciate at its proper value the assistance which the scientifically trained intelligence can give in the organisation of society and in the solution of social problems. Though in the main this indictment is quite true, it is certain that the blame lies not wholly with those to whom such censures are usually addressed, but that, on the contrary, some part of the responsibility should be imputed to the indifference of scientific critics to many questions of practical social interest—an indifference which prevents them from furnishing, as it should be their privilege and duty to furnish, the positive data needed for the passing of adequate measures of reform. That this has been the case in the particular instance of the drink problem would appear to be the moral enforced in the extremely interesting address recently delivered before the Society for the Study of Inebriety by the chairman of the Central Control Board (Liquor Traffic).

Lord D'ABERNON, in commenting on the relatively small results that have hitherto attended the efforts of legislators and reformers to abate the social evils of alcoholism, indicated as one of the chief causes of failure the absence of exact data regarding the fundamental factors of the problems of inebriety. As he pointed out, certain aspects of the physiological action of alcohol have been the object of most careful and exhaustive investigation. The problem of its food value has been settled, so far, at all events, as it can be settled in the present state of physiological knowledge. Much valuable work has been done with regard to the effect of alcoholic beverages on the activity of the digestive ferments, and numerous and important researches have been carried out to determine the influence of alcohol on the output of muscular energy. But when we come to consider its inebriating action and to inquire into the conditions which underlie the excessive use of alcohol and create the social evils of intemperance—we pass in a depressing way out of the region of scientific evidence. To illustrate this point Lord D'ABERNON cited a formidable list of lacunæ in our knowledge, many of these lacunæ referring, it may be noted, to matters which are of obvious practical importance in the

devising of measures for the arrest of intemperance. Thus, he observed, we have no reliable test of drunkenness, we have no positive data as to the effect of alcohol at various strengths and various degrees of dilution, we have no evidence regarding differences in the inebriating action of the several alcoholic beverages, no evidence as to whether alcoholic excess may not be related in certain cases to an abnormal need of fluid, quite irrespective of its alcoholic content. It was Lord D'ABERNON's complaint that on these and many other points his demands for information remained unanswered, there were statements of opinion, and very positive and dogmatic statements at that, but there were no data that could possibly be regarded as scientifically sound. At first sight this seems a startling and even an improbable assertion, but further scrutiny of the facts compels the admission, humiliating though it is, that the complaint is completely justified. The scientific literature of "the drink question," or, to speak more accurately, the literature which purports to be scientific, has unfortunately taken little account of such matters as we have referred to, for the most part it does not concern itself at all with facts of observation or experiment, and its spirit and method are rarely the spirit and method of positive science. The inebriety which it discusses, and discusses assuredly with much dialectical skill and ingenuity, is not the inebriety of common everyday experience—it is a product of deduction working on the hypothesis, assumed as axiomatically true, that the habit of alcoholic excess is always and everywhere the result of an innate specific craving for the sensations of drunkenness. To the practical inquirer, seeking for definite evidence on which to base effective remedial measures, this *a priori* speculation can obviously be of little use, and, as the results of legislative experiments in this matter should warn us, the attempt to apply conclusions, based on these very insecure premises, to the solution of the problems of alcoholism in any of its aspects, is not likely to be attended by conspicuous success. Fortunately we may feel certain that errors of this sort will not be repeated, the spirit which has been shown in the policy of the Central Control Board under the enlightened administration of Lord D'ABERNON gives full assurance that future legislation with regard to this question will be guided by principles of a less speculative nature and by knowledge more nearly connected with the real facts of the general issues. We have, indeed, already concrete evidence of the influence of this new spirit in the cautious and reasoned measures adopted by the Control Board with a view to decreasing chronic alcoholism. As Lord D'ABERNON points out, it has been established on definite evidence that the chronic poisoning, to which the more serious evils of intemperance are mainly due, is largely the result of the use of alcohol at frequent intervals throughout the working day, and it has, therefore, been one of the cardinal principles of the Control Board's policy to frame its restriction orders so as to break down this habit and tradition of industrial drinking. How has this policy worked? For

statistical purposes the most definite and reliable index of chronic alcoholism which we possess is the incidence of delirium tremens, and, since a large and stable proportion of all cases of the disease were under treatment in Poor law infirmaries and prisons, the records obtainable from these two classes of institutions should give clear evidence of the results of the restriction orders as regards the prevalence of chronic intoxication. And the evidence, on the figures quoted by Lord D'ABERNON, is certainly impressive. As a typical instance he takes the East London and Woolwich area, in this district the number of cases of delirium tremens treated in the infirmaries during the five months following the introduction of restriction orders amounted to 59, as compared with 109 in the corresponding period of 1915 and with 87 in 1914—and this reduction was even more marked and more regular in the females than in males, a strong suggestion that it is not to be attributed to the withdrawal from the civil population of men of military age. This result, and it is paralleled in other districts, is a very striking illustration of the degree in which alcoholism can be influenced by legislative measures, if only these measures are based on a foundation of real knowledge.

With such encouraging omens as we may find in the spirit and in the matter of Lord D'ABERNON'S address, we may reasonably hope that the biological factors which are fundamental in the problems of alcoholism will be the object of more serious and thorough observation than has been devoted to them in the past. In regard to this question in a very special degree the war has had an excellent educative effect on public opinion, and it may safely be asserted that there is at the present moment a general readiness, such as has never prevailed before, to acquiesce in any reasonable scheme for thorough and effective treatment. If this opportunity is to be fully utilised, and if the energy and goodwill that are now available for the work of reform are not to be frittered away in confused and futile effort, it is vitally necessary that the way for successful action shall be immediately prepared by a scientific and impartial study of the root facts.

Heat-Stroke

THE European in the tropics, especially if newly arrived there, is liable to suffer in two ways from the climatic conditions of the hot season. In the one case, heat stroke, the temperature of the body rises and there are signs of congestion and nervous irritation, in the other, heat exhaustion, there are pallor, fainting, and collapse. Heat-stroke is the commoner form. Although sometimes caused by the direct rays of the sun, especially where the new comer is unsuitably clad, it is much more frequently produced by the combination of high temperature and excessive moisture in a confined space. The risk is not great in the ordinary circumstances of life in the tropics, for most people are careful to protect themselves when out of doors and to adopt special arrangements for

cooling and keeping in motion the air of their dwellings, and this motion is a potent factor in removing heat from the body. The liability to heat stroke is very much greater in those who are in an exhausted state, whether due to overwork, fatigue, or illness, and such subjects are readily affected by a short exposure to unfavourable conditions. Even strong and healthy people succumb if subjected for a considerable time to air which is both hot and stagnant, especially if it is also impure and moist. The conditions met with in the engine rooms of vessels passing through the Red Sea at certain seasons of the year exactly exemplify the most dangerous air, and these conditions require the most careful attention to ventilation and to the escape of steam if tragedy is to be avoided. It has been experimentally shown by Dr J. S. HALDANE that if the wet bulb temperature exceeds 89°F in still air the body temperature begins to rise, and that the same effect is produced in moving air when the wet bulb reading approaches the body temperature.

Attention has been called to these conditions by the lamentable death, attributed to heat-stroke, of Sir VICTOR HORSLEY in Mesopotamia, and by the disaster to a trainload of soldiers in India. It appears from the official account that some Territorial drafts, amounting to 1013 men with 13 officers, arrived at Karachi in the first week of June and were there entrained for Lahore and Rawal Pindi in third class carriages. The train carried three medical officers, had two second class carriages fitted up as hospitals with fans, and was supplied with a coffee shop and a good quantity of ice. Thirty men were seated in carriages designed to accommodate 36, and 60 men in others which had a normal capacity of 72. Notwithstanding these arrangements, there occurred on the journey 136 cases of heat stroke, with 15 deaths. It is not stated whether the medical officers, like the soldiers they were accompanying, were new to the country, and had no special experience of the climatic conditions to which the men under their charge were likely to be subjected. Fortunately, at Lahore and Rawal Pindi a large number of medical men were available experienced in this tropical affection, and it may probably be attributed to this cause, and to the fact that ice had been provided on the way at different stations, that out of the 104 cases in the later stages of the journey there were only 3 deaths, against 32 cases with 12 deaths in the earlier. Certain incidents connected with the unfortunate journey are difficult to understand. Anyone familiar with the railway journey across the plains of India in May or June knows the distressing conditions under which it is made, even in first class carriages, accommodating only four persons in each, supplied with ample quantities of ice and iced water, and having additional cooling and freshening of the air provided by fans and rattles. Even so the ordeal may be grave for a European. In moving European troops at this season special precautions ought to be taken to protect the roofs of carriages from the effects of direct heat of the sun, and to avoid overcrowding.

Science and experience can suggest much to lessen the heat inside the carriages themselves. Such would be the normal preparation in India for the transport of troops under the supervision of men familiar with the conditions to be incurred. In cool weather 30 occupants to a third class carriage might not give rise to discomfort, but under conditions in which every soldier is giving off aqueous vapour at a rate of some 20 cubic feet per hour, while the air is stagnant, the wet bulb thermometer would easily rise to a dangerous point. The natives of India, who normally travel in third class carriages, are accustomed to the heat and wear fewer and lighter clothes, the fact that natives might with impunity have made the arduous transit cannot be used as an argument when we are considering the case of British soldiers in uniform. The unusual circumstances of this journey have been marked by the fact that on July 7th a senior officer from Army Headquarters, in company with Lieutenant-Colonel W. MOLESWORTH, I.M.S., left Simla for Karachi with instructions to visit all the stations along the line where fatalities had occurred, and to submit a full report after their return to Simla.

The amount of the mischief done may not be measured by the deaths alone, inasmuch as many of the soldiers attacked will be likely to suffer from a more or less permanent disability. It is clear that the circumstances should be made known without reserve. We are glad to learn that Mr. AUSTEN CHAMBERLAIN, Secretary of State for India, has directed the Government of India, that having fixed the responsibility for the tragedy, they are to hold the person or persons responsible to strict account.

Innotations.

No quid nimis "

SIR WILLIAM RAMSAY

PHYSICAL as well as chemical science has sustained a great loss in the death of Sir William Ramsay, which took place on July 23rd, in his 64th year. His career in the field of research was brilliant, if he is remembered mostly for his extraordinary attention to details and for a refinement of manipulative skill and attack which led to his important discoveries, it will also be seen that those discoveries were of vast significance. All along the conviction that there was value in ascertaining the nature of traces or residues was his guiding principle, and it led him aright. When we reflect that Sir William Ramsay with Lord Rayleigh made the simple observation independently that the nitrogen of the air was slightly heavier than the nitrogen obtained by chemical means, which ultimately led to the discovery of argon and its congeners krypton, neon, and xenon we must agree as to the importance of examining comparatively minute quantities. In reality these investigators were but pursuing the sequence of the classic experiment of Cavendish who found that when air was sparked there was always a small residue of gas which refused to disappear in the electric discharge in the presence of oxygen—refused in fact, to be burnt. This residue

contained the inert gases which Sir William Ramsay separated and identified. The importance of the infinitesimal was being exemplified at the same time by the discovery of radium in pitchblende by Madame Curie. She worked on tons of material in order to recover a grain or two of the substance radium, the isolation of which has completely revolutionised our ideas of energy and matter. These investigations were being conducted simultaneously and their concurrence led to very remarkable developments. Sir William Ramsay was not long in realising that the study of radium and its behaviour was likely to lead to further light being thrown on the nature of things, and to him largely we owe the conception of the degradation of elements. He demonstrated how radium's instability meant that it was constantly disappearing as such and appearing again in new elemental form. He mapped out the series of elements which succeeded the degradation of radium, and amongst others he proved the formation of helium. This was curious, as Sir William Ramsay was the discoverer of terrestrial helium. He had found it amongst the gases given off from a mineral called cleveite, and he showed that it exhibited the same powerful yellow line in the spectrum corresponding exactly with the line hitherto only known to exist in the solar spectrum. Sir William Ramsay now became absorbed in the study of disintegration and many of his colleagues think that the intense enthusiasm which he manifested towards this work undermined his physical strength. He may well be forgiven for his ardent attachment to these questions, for their investigation gave promise of establishing once and for all that the elements were merely modifications of one great family substance, and that, given the means, one element could be transmuted into another. As a matter of fact, the degradation of radium itself had already made out a case, but Sir William Ramsay evinced a great desire to show that the same phenomenon could be demonstrated with more familiar things. He reported once that in working with a copper salt under the stimulus of radium traces of lithium had appeared. The matter was never cleared up and no further contribution by way of confirmation or disproof was forthcoming, but in 1913 an announcement was made by two investigators, who were working quite independently of each other, that they had achieved clearly and definitely an example of the transmutation of elements. Hydrogen gas was introduced in small quantity into an X ray bulb and a rapid and continuous discharge was allowed to pass when both helium and neon, it was stated, made their appearance. The result, though again not since confirmed, was received with the greatest interest by Sir William Ramsay, who expressed his gratification that the theory of transmutation no longer rested for support on his word. His work on radio activity received a medical application. He undertook an exhaustive investigation into the properties of Bath waters, and successfully demonstrated that the one thing which distinguished these waters in particular was their remarkable radio active power. He could attach no therapeutic significance to the mere mineral constituents of the waters, which were much the same in kind and degree as those found in the London drinking supply. Later he pointed out in a paper contributed to our columns that the application of radium for therapeutic purposes was more effective in the shape of emanation or of niton than

as a salt of radium, on the ground that in the latter case there is considerable risk of loss of the precious radium. He described in this paper the introduction of niton into appropriate forms of apparatus—e.g., tubes, bulbs, and hollow flat discs—suitable for application. We have said enough to show Sir William Ramsay's great endowments and wide range of scientific equipment. He possessed a charming personality, and was extremely popular at University College, London, where he occupied the chair of chemistry from 1887 until 1913, and those who attended his lectures will ever remember his wonderfully lucid treatment of his subject. He had remarkable attainments in other directions, for he could deliver a lecture to either a German or French audience fluently in their own tongue, he was a gifted exponent of music and played both the piano and violin in delightful style. His death, at a comparatively early age, is a great loss both to science and society.

THE WAR AND ITS EFFECT UPON THE YOUNG

A CIRCULAR letter sent by the Home Office to the clerks to the justices throughout the country draws attention to a substantial increase in juvenile crime as shown by the police statistics of 17 of our largest towns. In the areas selected the total number of children and young persons charged with punishable offences in the three months December–February, 1914–15, was 2686, and in the same period, 1915–16, was 3596, an increase being noted in all the towns consulted. Moreover, and this is perhaps the most serious feature of the case, although there have been more charges of assault, malicious damage, gaming, and offences against the Education Act, the increased number of juvenile offenders is mainly caused by a rise of nearly 50 per cent in charges of larceny. It would indeed be deplorable if the standard of honesty among the young were to be seriously and permanently lowered at a time when their fathers and their brothers, many of the latter being little older than the culprits, are setting an example of bravery, self denial, and self sacrifice on the field of battle. In the circumstances, the Home Office rightly urges magistrates to do what they can to prevent adding to the criminal classes any who can be saved by the exercise of the powers of the bench under the Probation of Offenders Act, and reminds those who sit in judgment upon the young that parents may be made pecuniarily liable unless it is clear that no neglect on their part has conduced to the commission of the offence. Other matters of detail are also touched upon, such as the powers of magistrates to fine for carrying a gun without a licence boys who play with air guns, and to check the use of automatic gaming machines. Observations are also made as to the influence of cinema shows—indeed, the whole question of these entertainments is under consideration. It is clear that the loss of the restraining influence of parents who are fighting for their country or closely engaged in factories producing munitions is being felt to an appreciable extent in populous centres, so that in various respects we must hold the war responsible for lack of discipline among the younger members of the community. This is a position which it will require much energy and tact to combat. The circular letter of the Home Office suggests the employment of an increased number of female probation officers, but a doubt may be expressed as to

whether women experienced in social work and ready to undertake new functions may not at the present juncture be almost as difficult to discover as men. Again, reference is made to the breaking up of boys' clubs through the lack of managing staffs as being responsible for much mischief. Here again women and others, more or less new to the work, might help if they could be found disengaged. It will not be easy to obtain them, but our readers will do the country a service if they can recruit unoccupied persons of the right sort. It is too much to say that all of those whose energy, goodwill, and opportunity enable them to "do something" for their country's sake are doing it already. There are unoccupied hands and brains among us, and the time for which their work will be needed is short. For in the near future we pin our faith upon the young soldiers who will return to set an example and to take up the good work. They will find their influence doubled by the hero worship with which they will be regarded, and their increased knowledge of the benefits derived from honourable discipline will stand them in good stead.

AN IDEAL MECHANICAL HAND

WE learn from the Société Nationale de Chirurgie de Paris that an anonymous donor has offered to the society a prize of 50,000 francs, to be handed over to the maker of the mechanical apparatus which best supplies the place of the hand. The conditions laid down are as follows: "All competitors must belong to allied or neutral nations. They are to present to the society mutilated men who have been using their apparatus for at least six months. The Société de Chirurgie will experiment with each apparatus on mutilated men for the length of time it thinks fit. The apparatus rewarded is to remain the property of its inventor. The competition will be closed two years after the end of the war." MM. Faure, Kurmisson, Quénu, Rieffel, and Rochard form the committee selected by the society to deal with the competition, and those wishing to compete should send the apparatus and description to the Secretary General of the Société Nationale de Chirurgie, 12, Rue de Seine, Paris.

ANTHRAX AND POSSIBLE PRECAUTIONS

AT a recent inquest held by Dr F. J. Waldo, coroner of Southwark, upon the body of a waterside labourer it was proved that the man had died of cutaneous anthrax contracted in the course of his work in a warehouse where wool from Persia and China was handled. The evidence also showed that on the wool floor where the deceased worked, as at the wharf with which the warehouse was connected, there was general ignorance among those employed both with regard to the possibility of infection with anthrax from the wool and to the nature of the disease. Dr Waldo, with invariable readiness to seize the opportunity for making a useful recommendation, explained the matter to the jury, with the aid of the facts before them and of the explanations given by the expert witnesses called. As a result the following rider was appended to the verdict—

We (the jury) think that the provisions of the Factory and Workshop Acts should be extended—or enlarged—so as to apply to the wharves and warehouses and other places where foreign or suspect wool, hides, skins, horse and goat hair, pigs' bristles, and other material liable to be infected with anthrax are handled and dealt with, and that the excellent preventive regulations including placards in picture form—issued by the Home Office—should be compulsorily exhibited

and enforced for the information and well being of workers in such wharves and warehouses

Nearly two years ago, in December, 1914, an inquest was held at Southwark by Dr Waldo on the body of a butcher who had died from cutaneous anthrax in Guy's Hospital, when the jury added the following rider to their verdict—

We (the jury) recommend that anthrax should be universally (not only in London, but at Croydon, Mitcham, and many other districts throughout the country, including Bradford and the West Riding of Yorkshire—the chief seat of the wool trade) placed on the list of dangerous infectious diseases compulsorily notifiable by medical men in attendance on such cases, to the medical officer of health of the district in which the patient was under treatment, and, secondly, that all deaths from anthrax should be reported compulsorily to the coroner in whose district the body lies

Dr T M Legge, chief medical inspector of factories, stated in his evidence at the more recent inquest that his work was confined to factories and work shops, but that the reporting of cases of anthrax occurring in warehouses could only be "encouraged." He said "Their medical officer is obliged to report to me only if the disease is contracted in a factory or workshop, but not in warehouses, except in the County of London. The occupier also has to report to the district inspector of factories and to the certifying surgeon of factories and workshops, but not warehouses, which may escape altogether." He further expressed the opinion that it would be most useful to hold inquests upon deaths by anthrax as an effective way of calling attention to the danger and as a means of prevention. Dr Legge bore witness also to the usefulness of illustrated warnings, hung where workmen constantly have them before their eyes, in order to secure prompt recognition of pimples likely to be those associated with the disease. Recently the attention of the Home Office has been called to the opinions expressed by the juries in the two cases above referred to, and the matter is not likely to be overlooked. A Departmental Committee is considering the subject of anthrax in connexion with the wool industry, and its recommendations will, no doubt, take into account the state of affairs which the two inquests held by Dr Waldo have shown to exist. The number of workmen who suffer in the course of the year from anthrax poisoning may not be large, but it is right and reasonable that the fullest possible protection should be given to all likely to be exposed to so deadly a disease. Prevention and the earliest possible notification to all concerned are the objects aimed at by the Factory and Workshop Acts, and it is desirable that they should be hampered as little as possible by technical limitations as to the precise buildings or industries governed by them. Meanwhile, the duties of medical practitioners who may find themselves in attendance upon cases of anthrax contracted in a factory or workshop are laid down in Section 73 of the Factory and Workshop Act, 1901

CHILD WELFARE

THE effect of the war in diminishing the personnel of the school medical services may become serious. We learn from a statement by Mr Arthur Henderson the President of the Board of Education, that down to March, 1915, there were 850 school medical officers, of whom no less than 300 have now joined the military services. This being the case it is more important than ever that the work dealing with maternity and infant

care in general should be so perfectly coördinated as not to result in overlapping or the waste of public money. In this connexion attention may be called to an article by Miss Annie E Barnes,¹ secretary of the Child Welfare Enquiry Office, in which it is urged that the time has come for the adoption by all local health authorities of a definite scheme for infant welfare, and that this scheme should include under one efficient controlling force all the efforts for the promotion of the well being of mothers and young children. Miss Barnes points out that at present it is possible for half the efforts in these directions to be provided by the health authority of the district and to receive their grants from the Local Government Board, while the remainder may be provided by voluntary means and receive their grants from the Board of Education. Mr Henderson stated that the school medical services included not only medical inspection of school children, but the treatment of certain affections of the throat, eyes, ears, and skin, and that there were now in existence 350 school clinics. We agree with Miss Barnes that the institutions which are an integral part of the general work of reducing infant mortality should be under the supervision of the health rather than the education authority, and so be brought into the general plan of campaign.

PAYMENT FOR CERTIFICATION IN IRELAND

WHEN an agreement was arrived at between the medical profession and the Irish Insurance Commissioners last December as to a scheme for the certification of insured persons one point was left over for discussion when some experience of the scheme would have been gained. A conference was held recently to deal with this reserved question—namely, the method of distribution of the Treasury grant—and the Irish Medical Committee decided to accept the proposal of the Commissioners. Each insurance area is to have its own pool of funds which are to be divided among the several medical men certifying according to the work done by each. The method of calculating the work done is ingenious, if a little complicated. The unit will be a certificate, but each initial and each final certificate will count as one and a half, certain other special certificates will count as two. Before proceeding to distribute the pool the Commissioners will count the average number of certificates per case issued by each certifier, and a deduction will be made from the number of each certifier who has issued more than what is found to be the average number of certificates per case for the particular area.

A NATIONAL SCHEME OF PHYSICAL TRAINING

A COURSE of lectures on a national scheme for physical training has recently been delivered in Manchester. The scheme includes the protection of infant life by the institution of day nurseries. Major R Tait McKenzie, R.A.M.C., professor of physical education in the University of Pennsylvania, spoke on the necessity for a national scheme of physical education. He urged that the physique of most of the recruits whom he saw in training for the Army during the summer had been allowed to take care of itself. If they had entered upon training with a soundly developed body, their chances of survival in the

¹ Englishwoman, July 1916.

field would have been greatly increased. That they had risen to the emergency as well as they did was a tribute to their spirit and courage, but it took more than moral stamina to endure the long march with a heavy pack, to hold the rifle with a steady arm, and to discharge their other militant duties. Major McKenzie contended that it was simply committing national suicide to neglect the complete education of every child's physical powers at the present time. Dr Barbara Tschakowsky, in an address on infant welfare, made a strong appeal on behalf of infant life, based on the obvious lessons taught by the war. At a later meeting promoted by the Manchester and Salford Council for Day Nurseries and Nursery Schools it was stated that the council was considering two schemes—one, in which the co-operation of employers will be sought, for temporary day nurseries or "war nurseries," situated near works where numbers of married women are employed, and another for the establishment of permanent day nurseries, to be combined, whenever possible, with nursing schools.

THE COCAINE HABIT

UNTIL the war there does not appear to have been any substantial increase in the addiction to cocaine in this country, and the recent introduction of the habit among our troops is probably correctly attributed to the Canadians, whose example has been followed at first out of mere curiosity. In the ranks cocaine is usually taken in the form of snuff, known as "snow," and the hypodermic method is not often used. The victims of the habit allege that cocaine is taken to replace alcohol when that is unobtainable in sufficient quantities, or, if taken in the desired amount, would lead to punishment. It is well known that drug habitues ring the changes for various causes between alcohol, morphia, opium, and cocaine, sometimes doubtless in the hope of breaking a habit, at other times because the particular poison desired is unobtainable. The cocaine habit is largely prevalent in various parts of America, and has more recently invaded India. Now that the practice has been introduced among our young men there is a grave risk that the habit will spread, especially if the sale of liquor continues to be restricted, unless there are stringent precautions taken to stop the sale of the drug.

THE medical profession has sustained a severe loss in the death at sea on July 17th, of Dr Arthur Hugh Lister, C.M.G., physician to the Aberdeen Royal Infirmary. Lieutenant Colonel Lister was returning from Alexandria where he was in medical charge of the 19th General Hospital.

THE death from wounds was announced last week of Mr R. W. Michell, Captain, R.A.M.C. (T.), M.D. Cantab., F.R.C.S. Eng. He was equally well known in scientific and athletic circles, and his death will cause a sense of personal loss to a very large circle of Cambridge friends.

THE death is announced, in his 82nd year, of Mr Thomas James Walker, M.D. Lond., F.R.C.S. Eng., V.D., consulting surgeon to the Peterborough Infirmary, and one of the most widely known practitioners in the provinces.

A SERIOUS DEFECT IN SOME OF THE REGISTERED HOSPITALS FOR THE INSANE

BY HENRY RAYNER, M.D. ABERD.

THE registered hospitals for the insane rank amongst the finest of English charitable institutions. Their admirable and successful management is vouched for by the favorable reports of the Commissioners in Lunacy for many years past, and it would be difficult to praise too highly the medical treatment of the patients committed to their care. In one point only do they appear to fall short of the work which they were intended to fulfil, but that is one of a more serious and vital character, to which the attention of the public and of the boards of management of these institutions should be promptly given if they are to be prevented from departing still further from the object for which they were primarily founded—viz., the charitable assistance of persons of the educated class suffering from mental disorder.

The Commissioners in Lunacy have on more than one occasion drawn attention to the small amount of charitable assistance afforded by these institutions, and in the first report of the Board of Control (for the year 1914) recently issued, there are the following paragraphs—

The registered hospitals still continue to be conducted on good lines and in an enlightened manner and as heretofore they form a very important feature in the lunacy administration of the country. It is however necessary to repeat the admonition that as these institutions were originally founded upon a charitable basis as large a proportion of cases upon unremunerative terms should be received as is consistent with the reasonable financial stability of the hospitals and that the latter should not degenerate into luxurious homes for wealthy patients only or principally for them.

In the entries made by the members of the Board of Control at their visits to ten of the principal registered hospitals there is a record of the percentage of patients received in each (1) free of all payment, (2) on weekly payments of less than 10s., (3) of from 10s. to 21s., (4) from 21s. to 42s., and (5) from 42s. upwards.

From the data thus given it appears that in the six more costly asylums whose weekly rates ranged from £3 7s. 7d. to £1 18s. 3d., having an income from patients' payments of over £286 000, a total of less than 14 patients were received without payment, 58.1 under 10s. per week, and 149.96 at from 10s. to 21s. out of a total of 1622 patients whilst in the four hospitals whose rates vary from £1 15s. 4d. to £1 6s. 7d. weekly with an income from patients of £40 887 19 93 were received without payment 23.73 under 10s. and 192.84 at from 10s. to 21s. in a total of 534. The total incomes from all sources in the two groups approximate to £300 000 and £50 000 and the average of the rate of maintenance is £2 14s. 8d. and £1 11s. 10d. respectively per hospital. In tabular form and discarding fractions the actual charitable assistance in the two groups is—

	No payment	Under 10s.	10s. to 21s.
1st group	14 patients	58 patients	150 patients
2nd "	24 "	24 "	193 "

From these data it may be gleaned that the hospitals having the lower rate of expenditure do a very large amount of charitable work in the number of persons assisted equal at least in this respect, to their more wealthy brethren and in relation to income nearly six times as much. They show that even with small means much may be done.

The hospitals with the high rate of maintenance might put forward the plea that all patients received on payments under the weekly maintenance rate, were charitably assisted to the extent of the difference between this and their actual payments, for example, that in a hospital with a weekly rate of maintenance of £3 a patient paying nothing would be benefited to the extent of £3 per week and one paying £2 10s. to the extent of 10s. per week. This however is an unsound way of looking at it. In the first place a patient able to pay £2 10s. ought not to need charity being able to obtain perfectly satisfactory care (as seen in the second group of hospitals) for an average of £1 11s. 10d. per week, and even less than this in the private annexes of county institutions. But they do not obtain the full value of the higher rate of maintenance since the highly paying patients paying perhaps as much

as 8 and even 12 guineas per week, may cost actually 5 or 9 guineas per week if they get fair value for their money. The result of this must be that the less highly paying patients are not maintained at anything like the average rate of maintenance, and are certainly not charitably assisted, as above suggested, to the extent of the difference between their payments and the maintenance rate. If an estimate is made, however, on the basis that a patient is charitably assisted to the extent by which his payments fall below £1 per week, then patients paying nothing are benefited to the amount of £1, those paying less than 10s. to about 15s. those paying between 10s. and 21s. to about 5s. per week. It will appear that one of these institutions out of its vast income would give charitable aid to the extent of less than 2 per cent., whilst one of the less wealthy group would give aid by nearly 20 per cent. of its income. The total monetary aid given by the two groups on this estimate would closely approximate. If a similar estimate is made on a weekly rate at which charitable aid commences at 25s. a result still more unfavourable to the more wealthy group of hospitals is arrived at in the contrast of the relative percentage of charitable assistance and income.

It would appear therefore, that these rich institutions under existing conditions are a benefit to the wealthy and well-to-do classes rather than to the poorer members of the same social standing. Wealthy patients are often saved considerable expense (one person to my knowledge having an income of £4000 or £5000 per annum being maintained for £400 a year) but this assistance appears to result in the exclusion of many poor persons, who are consequently driven into or obliged to remain in pauper asylums as paupers. That there are numerous insane persons needing the aid of such institutions as the registered hospitals is shown by the report of the Board of Control which says (p. 3) that—

Many classed as paupers are not strictly speaking paupers in the generally accepted sense for a certain number of them are actually maintained by relatives, who refund to the Poor law guardians the whole cost of maintenance.

The fact that in a total of 9958 private patients in England and Wales there are only 3879 males shows that there must be a large number of males of the private class who not having wage earning relatives to support them (as in the case of the females) become inmates of pauper asylums. Were this not the fact, the numbers of male and female private patients should approximate much more closely.

There can be no doubt either from statistics or from observation of the inmates of pauper asylums, that there are in them numerous persons of the educated classes who require charitable assistance and treatment under conditions and with associations more nearly approaching to their normal mode of life. Such help is not only conducive to their comfort and to that of their friends but is also helpful in treatment. The want of it is often a source of grievous suffering and a drawback to the prospect of recovery.

The admonitions of the Commissioners in Lunacy who possess from the Board of Control no actual power of insistence should be followed by some definite indication of the mode in which this much needed reform should be carried out. It is certain that the managers of these institutions are desirous of doing charitable work and, if it is fully proved to them that the provision of palatial accommodation and luxurious menage (in rivalry with other institutions or for the purpose of attracting wealthy patients) are not conducive to this purpose they will be ready to adopt any suggestions made by the Board of Control and loyally attempt to carry them out.

The statistics quoted above and the experience of the private annexes of pauper asylums suggest that one plan of adjusting the charitable activities of the institutions might consist in demanding that all receipts above a certain mean should be expended in charitable assistance to patients unable to contribute that sum for their maintenance. 25s. shillings per week, or something more in some hospitals would probably yield the most satisfactory results. It is of course a matter for the decision of the Board of Control. The general conclusion must be drawn from the preceding facts that although the registered hospitals are conducted on good lines and in an enlightened manner [to quote the report] some of them lamentably fail to perform the charitable function for which they were originally

founded, and have in some instances largely degenerated into luxurious homes for wealthy patients."

When it is considered that on an income approaching £300 000 in the six more expensive hospitals the really charitable help, whether calculated on the number of persons assisted or on the actual monetary aid, is so infinitesimal, while the actual luxurious expenditure is so large, we are inevitably reminded of Falstaff's "one halfpennyworth of bread to an intolerable deal of sack."

FORTY-FOURTH ANNUAL REPORT OF THE LOCAL GOVERNMENT BOARD

THIS report has now been issued in three sections, of which Parts I. and III. concern medical readers.

Poor-Law Administration

Under Part I the administration of the Poor law is dealt with, the Unemployed Workmen Act, the Old Age Pensions Acts, and the special work arising out of the war in connexion with prevention and relief of distress, reception and accommodation of war refugees, distribution of the gifts from the dominions and colonies &c. It may be remembered that in the early days of the war it was generally thought there was likely to be serious distress in this country as a result of unemployment and that steps were taken to combat this evil by the appointment of the Government Committee on the Prevention and Relief of Distress, the organisation of the country under local representative committees and the establishment of the National Relief Fund in response to an appeal from H.R.H. the Prince of Wales. At the outset the Government Committee laid down the wholesome principles that distress should, wherever possible be met by the provision of work, that the work provided should be of a useful nature, and that relief by doles should be restricted within the narrowest limits. In order to fulfil these requirements steps were taken to secure the co-operation of the principal spending departments of the Government with a view to the spreading of contracts, and arrangements were made for useful work to be done in connexion with the construction and repairing of roads as well as in other branches of public work. Fortunately, the unemployment due to the dislocation of industry at the outbreak of war was of short duration, and few of the schemes of work which had been prepared had to be used. The initial unemployment was soon neutralised by the number of workmen who joined the naval and military forces, while the depression experienced in certain trades was counteracted by the great activity in the industries engaged in fulfilling Government orders. At the end of October employment had reached practically the same level as in the period before the war, and by the early part of 1915 the situation had so far improved that the question of unemployment generally had almost disappeared. The total number of persons in receipt of Poor law relief in England and Wales was smaller at the end of the year 1914-15 than at the end of the preceding year. Exclusive of pauper lunatics in lunatic asylums the total number of persons in receipt of relief at the end of 1914-15 was 652,152, showing a decrease of 19 968, as compared with the figure at the end of 1913-14, which amounted to 672,120. Further, pauperism in 1914-15 was considerably less than the average for the five years 1909-10 to 1913-14 inclusive. Apparently those brought up in Poor law institutions show no lack of patriotism, for we are told in this report that large numbers of such men have joined the colours and are serving either in the Navy or Army. The list includes three who have earned the V.C. and a number who have won various other military honours.

The gross expenditure on relief of different classes of paupers exclusive of sums repaid by the Poor law authorities on account of non-settled poor amounted for the year to £15 373 668 apportioned as follows indoor paupers £8 972,655, outdoor paupers £3 053 433, pauper lunatics £2 792,821. The remainder consisting of such establishment and other charges as cannot readily be apportioned amounted to £554 746. It will be remembered with pride that the dominions and colonies overseas sent gifts of large quantities of foodstuffs to this country shortly

after the outbreak of war. In view of the speedy recovery in industrial activity alluded to above it soon became unnecessary to reserve the whole of this supply of food for the relief of distress at home and a considerable quantity of flour was made over to the Commission of Relief in Belgium at a price to be fixed by the Board of Trade, while a very large part of the balance of the flour and other gifts was handed over to the Army Council for the use of the troops. The British Medical Association and the Pharmaceutical Society put forward and coöperated in a scheme for the provision of free medical attendance and the supply of medicines and appliances at cost price to dependents of men serving with the colours, except to those whose circumstances were such as to render such assistance unnecessary. In connexion with war refugees, it is stated in this report that the War Refugees Committee had, at March 31st, 1915, despatched 87,729 refugees to the local committees for hospitality in their respective areas. Refugees arrived from the continent both by the ordinary passenger boats and by special services which had been arranged for the transport of Belgian refugees from Holland. Dr Reginald Farrar, one of the medical inspectors of the Local Government Board, took charge of a branch office in Flushing, and showed great zeal and devotion in the work of examining and embarking the refugees and looking after their various wants.

Public Health Treatment of Tuberculosis

Part III of the report deals with (a) public health and local administration, (b) county council administration, (c) local taxation and valuation. The subject dealt with under (a) will be of greater interest to readers of this journal than those under (b) and (c), though, as the information given under (a) relates mainly to the year ended March 31st, 1915, much of it is rather ancient history to those who follow closely the development of public health work. The report of the Board's medical officer appeared, as in previous years, as a supplement to this report and a review of its contents appeared on p. 638 of THE LANCET of March 18th.

The section of the report dealing with the treatment of tuberculosis has reference to the period ended June 30th, 1915, and applies to England only. Up to the outbreak of war steady progress was being made with the development of approved schemes of treatment, and the large majority of counties and county boroughs had adopted schemes which had received the approval of the Local Government Board. A considerable number of men have been discharged from the Army suffering from pulmonary tuberculosis, and, as the large majority of soldiers are insured persons, arrangements are now in operation whereby, in the case of insured men discharged from the Navy or Army suffering from tuberculosis and requiring treatment in a residential institution, the necessary accommodation is found by the Insurance Commission or by the appropriate Insurance Committee. As many workhouses and infirmaries have been temporarily taken over by the military authorities for use as hospitals, it has been necessary for the local authorities in certain districts to increase the accommodation provided by them for the treatment of tuberculosis in order to provide accommodation for tuberculous persons usually maintained in institutions belonging to the guardians. The Local Government Board has approved of the appointment of 131 tuberculosis officers by county councils, of 100 by county borough councils, and of 7 by joint committees of county and county borough councils. As a large majority of the tuberculosis officers are men of military age, the demands for their services on duties immediately connected with the war have naturally been great, and 69 of these officers had, up to June 30th, 1915, resigned either temporarily or permanently in order to render war service. The loss, thus occasioned, of nearly 33 per cent of the responsible clinical officers naturally involved some dislocation of the machinery for dealing with tuberculosis, and temporary measures had to be devised in order to secure that the most important aspects of the work should be interfered with as little as possible. Such temporary measures included the appointment of suitable medical practitioners to act as temporary tuberculosis officers, or the utilisation of the part-time services of officers engaged in other public health work. In this connexion the Board state that they have been impressed by the willingness of the medical profession as a whole to put their services at the disposal of the nation in whatever capacity might be deemed most

useful. In regard to the financial aspect of the treatment of tuberculosis, it appears that the total maintenance grant paid during the year ended March 31st, 1915, was £155,799 5s. 9d. The share of England in the capitation grant of £1,500,000 which was made available by the Finance Act, 1911, to aid the provision of sanatoria and other institutions for the treatment of tuberculosis amounted to £116,156, and up to June 30th, 1915, grants amounting to £408,669 had been definitely promised towards the cost of institutions forming parts of schemes approved by the Local Government Board. Of this sum £195,279 had been actually paid.

The question of conferring upon local authorities farther powers in regard to the compulsory isolation of persons suffering from pulmonary tuberculosis who are in a highly infectious condition is discussed in this report. It appears that some nine local authorities have already obtained such special powers under local Acts, but that it has not yet been found necessary to make any extensive use of them. The opinion is expressed that the matter is one which requires careful consideration.

Vaccination Unsatisfactory Position

The section of this report dealing with vaccination is far from cheerful reading. The number of certificates of successful vaccination received during the year 1914 was 404,816, as against 430,470 in 1913, and the number of certificates of exemption 321,313, as against 308,235 in 1913. The number of persons on whom successful primary vaccinations were performed by the public vaccinators during the year ended Sept. 30th, 1914, was 301,416, of whom 284,227 were infants under 1 year of age. The latter number includes 4223 children who were vaccinated by medical officers of workhouses and infirmaries. During the same period 13,651 successful revaccinations were performed at the cost of the rates. The total number of births registered during the year ended Sept. 30th, 1914, was 882,333, and, when this number is compared with the number of children under 1 year of age (284,227) who were vaccinated by the public vaccinators, it may be assumed that about 32.2 per cent of the children born in the year were vaccinated at the public expense. This ratio of 32.2 per cent of successful primary vaccinations by public vaccinators to the total number of births registered constitutes the lowest on record since 1898. On the other hand, there are indications that this country may have to face an epidemic of small pox before very long. In certain parts of Europe, Asia, and America at the present time small pox has assumed epidemic prevalence, and even in England and Wales there have been an unusual number of scattered cases during the last few months. In these circumstances, with an ever increasing number of unvaccinated persons added annually to the population, the future is not without its anxieties.

THE SERVICES

ARMY MEDICAL SERVICE

To be temporary Colonels: Major F F Burghard, C.B., R.A.M.C. (T.F.), and Temporary Lieutenant-Colonel T C English.

ROYAL ARMY MEDICAL CORPS

To be temporary Majors: Major T M Carter (T.F. Reserve), Captain C A Pannett, R.A.M.C. (T.F.), and Captain P Hamill, R.A.M.C. (T.F.).

Temporary Captain W Ormsby relinquishes his commission. Temporary Captain G A Borthwick relinquishes his commission on account of ill health.

Temporary Lieutenant Francis P Kennedy relinquishes his commission.

Temporary Lieutenants relinquish their commissions on account of ill health: W E Huff Hewitt and G P Sheehan. C C Goodall to be temporary Honorary Lieutenant whilst serving with the British Red Cross Hospital, Netley.

F W Gwyder to be temporary Honorary Lieutenant whilst serving with St John Ambulance Brigade Hospital.

Canadian Army Medical Corps. The undermentioned Captains (Canadian Militia) to be temporary Captains: W F Jackson, D L Fee, H A Dixon, E B Moles, A W Knox, E E McPherson, H C Wallace, J L McDougal, H A Hessian, A J McCallum, and W C Givens. Lieutenant J D Adamson (Canadian Militia) to be temporary Captain.

Supplementary to Regular Units or Corps: Royal Army Medical Corps—Cadet J N L Blamey, University of London Officers Training Corps, to be Lieutenant.

TERRITORIAL FORCE

Royal Army Medical Corps

North Midland Casualty Clearing Station Lieutenant A. Young to be Captain
 Highland Mounted Brigade Field Ambulance T. L. Ashforth to be Lieutenant
 Northumbrian Field Ambulance, To be Lieutenants W. Nevill and J. R. Mitchell
 South Wales Mounted Brigade Field Ambulance Lieutenant J. O. Outhbertson to be Captain
 Scottish General Hospital Captain H. J. Stiles is seconded whilst holding a temporary commission in the R.A.M.C.
 London Field Ambulance Lieutenant (temporary Captain) E. Sandlands to be Captain
 Attached to Units other than Medical Units—Lieutenant F. W. White to be Captain H. W. Beedham to be Lieutenant

ROYAL NAVAL VOLUNTEER RESERVE

To be temporary Dental Surgeons R. R. Adams and F. H. Richards

THE ORDER OF THE NILE

The King has given permission to Lieutenant-Colonel F. F. Carroll, R.A.M.C., Principal Medical Officer, Egyptian Army, and to Major J. Powell, R.A.M.C., late Egyptian Army, to accept and wear the decoration of the Third Class of the Order of the Nile conferred upon them by the Sultan of Egypt

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

In the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 8104 births and 3675 deaths were registered during the week ended Saturday, July 22nd. The annual rate of mortality in these towns, which had declined from 12.6 to 10.7 per 1000 in the four preceding weeks, rose in the week under notice to 11.1 per 1000 of their aggregate civil population, estimated at 17,312,295 persons for the year 1915. During the 13 weeks of last quarter the mean annual death rate in these towns averaged 14.3, against 13.8 per 1000 in London. Among the several towns the death rate last week ranged from 5.0 in Rhondda, 5.1 in Enfield, 5.5 in Southend-on-Sea, 5.7 in Lincoln, and 6.0 in Reading, to 15.3 in Bootle, 15.4 in Brighton, 15.5 in Barnsley, 16.0 in Exeter, and 18.6 in Gateshead.

The 3675 deaths from all causes were 123 in excess of the number in the previous week, and included 212 which were referred to the principal epidemic diseases, against numbers declining from 335 to 222 in the seven preceding weeks. Of these 212 deaths, 69 resulted from measles, 46 from infantile diarrhoeal diseases, 43 from diphtheria, 42 from whooping-cough, 17 from scarlet fever, and 5 from enteric fever but not one from small pox. The annual death rate from these diseases was equal to 0.6, against 0.7 per 1000 in each of the five preceding weeks. The deaths attributed to measles, which had been 68, 60, and 62 in the three preceding weeks, fell to 59, and included 16 in London, 9 in Liverpool, 6 in Sheffield, and 4 each in West Ham, Wolverhampton, and Birmingham. The deaths of infants (under 2 years) from diarrhoea and enteritis which had been 50, 54, and 51 in the three preceding weeks, fell to 46 of which 12 occurred in London and 4 in Birmingham. The fatal cases of diphtheria, which had been 29, 36, and 47 in the three preceding weeks, fell to 43, 8 deaths were registered in London, 6 in Bradford, 4 in Stoke-on-Trent and 3 in Wolverhampton. The deaths attributed to whooping-cough, which had been 55, 61, and 40 in the three preceding weeks, slightly rose to 42, and included 8 in London, 7 in Birmingham, and 6 in Manchester. The deaths referred to scarlet fever, which had been 13, 4, and 15 in the three preceding weeks, rose to 17, of which 5 were recorded in London and 2 in Salford. The fatal cases of enteric fever, which had declined from 13 to 7 in the four preceding weeks, further fell to 5, but showed no excess in any particular town.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had declined from 1303 to 1236 in the four preceding weeks, had further fallen to 1216 on Saturday last. 112 new cases were admitted during the week, against 162, 170, and 150 in the three preceding weeks. These hospitals also contained on Saturday last 1266 cases of diphtheria, 153 of measles, 162 of whooping-cough and 43 of enteric fever, but not one of small pox. The 896 deaths from all causes in London were 7 in excess of the number in the previous week and corresponded to an annual death rate of 10.3 per 1000. The deaths referred to diseases of the respiratory system which had been 107, 95 and 117 in

the three preceding weeks, fell to 99 in the week under notice.

Of the 3675 deaths from all causes in the 96 towns, 176 resulted from violence, 326 were the subject of coroners' inquests, and 1187 occurred in public institutions. The causes of 29, or 0.8 per cent, of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Manchester, Sheffield, Leeds, Bristol, and in 63 other smaller towns. Of the 29 uncertified causes, 7 were registered in Liverpool, 5 in Birmingham, 3 each in South Shields and Gateshead, and 2 in Hull.

HEALTH OF SCOTCH TOWNS

In the 16 largest Scotch towns with an aggregate population estimated at 2,372,000 persons at the middle of this year, 1141 births and 511 deaths were registered during the week ended Saturday, July 22nd. The annual rate of mortality in these towns, which had been 12.6, 12.4, and 12.6 per 1000 in the three preceding weeks, fell to 11.2 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death rate in these towns averaged 15.3, or 1.0 per 1000 in excess of that recorded in the large English towns. Among the several towns the death rate last week ranged from 3.4 in Coatbridge, 6.2 in Ayr, and 6.4 in Kirkcaldy to 13.3 in Edinburgh and in Dundee, 13.8 in Falkirk, and 14.6 in Leith.

The 511 deaths from all causes were 60 below the number in the previous week, and included 39 which were referred to the principal epidemic diseases against 46 and 44 in the two preceding weeks. Of these 39 deaths, 17 resulted from measles, 7 from infantile diarrhoeal diseases, 6 from diphtheria, and 3 each from enteric fever, scarlet fever, and whooping-cough, but not one from small pox. The annual death rate from these diseases was equal to 0.9, against 0.6 per 1000 in the large English towns. The deaths attributed to measles, which had been 28, 19, and 18 in the three preceding weeks, numbered 17 last week and included 9 in Glasgow, 3 in Leith, and 2 in Edinburgh. The deaths of infants (under 2 years) from diarrhoea and enteritis, which had been 13, 5, and 8 in the three preceding weeks, were 7 last week, of which 5 occurred in Glasgow. The fatal cases of diphtheria, which had been 5, 5, and 3 in the three preceding weeks, rose to 6, and included 2 in Edinburgh. The 3 deaths from enteric fever were recorded in Glasgow, Dundee, and Clydebank respectively. The 3 deaths attributed to scarlet fever were 2 below the average in the three preceding weeks, and were registered in Glasgow, Motherwell, and Ayr respectively. The fatal cases of whooping-cough, which had been 5, 8, and 8 in the three preceding weeks, fell to 3, and comprised 2 in Glasgow and 1 in Paisley.

The deaths referred to diseases of the respiratory system, which had been 57, 64, and 50 in the three preceding weeks, rose to 62 in the week under notice but were 10 below the number registered in the corresponding week of last year. The deaths from violence numbered 22, against 23 and 16 in the two preceding weeks.

HEALTH OF IRISH TOWNS

In the registration area of Dublin 206 births and 116 deaths were registered during the week ended Saturday, July 22nd. The annual rate of mortality, which had been 17.9, 17.6, and 18.8 per 1000 in the three preceding weeks, fell to 15.2 in the week under notice, against 10.8 and 11.1 per 1000 in London and Glasgow respectively.

Of the 116 deaths at all ages, 23 related to infants under 1 year and 25 to persons aged 65 years and upwards. Three deaths of infants (under 2 years) were referred to diarrhoeal diseases, and 1 each to measles and diphtheria.

The causes of 10 deaths were uncertified, and 3 others were the subject of coroners' inquests, while 51 or 44 per cent, of the total deaths occurred in public institutions.

During the same period 165 births and 109 deaths were registered in the city of Belfast. The deaths corresponded to an annual rate of 14.6, or 0.1 per 1000 less than in the previous week, and included 16 of infants under 1 year and 23 of persons aged 65 years and upwards. Two deaths were referred to measles, and 1 each to enteric fever and whooping-cough. The causes of 3 deaths were the subject of coroners' inquests, and 32 deaths occurred in public institutions.

NATIONAL WELSH MEDICAL SCHOOL—A deputation from the Council of the University College of South Wales has been appointed to urge the Ministry of Munitions to permit the building of the department of public health and preventive medicine simultaneously with the physiological block. The deputation includes the President and Vice-Presidents of the Council and the Principal, Dr. E. H. Griffiths.

Obituary.

SIR VICTOR HORSLEY, M B, B S LOND, F R C S ENG,
F R S

COLONEL CONSULTANT, MEDITERRANEAN EXPEDITIONARY FORCE;
CONSULTING SURGEON UNIVERSITY COLLEGE HOSPITAL
SURGEON TO THE NATIONAL HOSPITAL FOR
PARALYSIS AND EPILEPSY

—We regret deeply to chronicle the death of Sir Victor Horsley, while he was acting as consulting surgeon to the British Forces in Mesopotamia. His eminent scientific position and the numerous social causes of which he was the champion made him one of the best known as well as one of the most widely admired of our professional leaders, and the number of public men, private friends, colleagues, and pupils is really great to whom Horsley's sudden death has come as a shock when recalling his vigorous and forceful personality.

Victor Alexander Haden Horsley was born in Kensington in 1857, the son of the late J O Horsley, the well known painter. He was educated at Cranbrook School and University College Hospital, where his career was an unbroken line of academic successes. He qualified as M B Lond and B S in 1881, winning the University scholarship and the gold medal in surgery. Two years later he took the F R C S Eng, and for a time was occupied with minor posts in connexion with the hospital, although he was already engaged upon original physiological work. From 1884 to 1890 he was Professor Superintendent of the Brown Institution, and while he occupied that post he made the elaborate and exhaustive experiments which went to show that myxœdema was caused by absence of the thyroid gland. In 1885 he was elected assistant surgeon to University College Hospital, and in the following year surgeon to the National Hospital for Paralysis and Epilepsy. In 1893 he became full surgeon to University College Hospital, but resigned four years later, being elected consulting surgeon. From 1891 to 1893 he was Fullerian Professor at the Royal Institution, and from 1893 to 1896 he was Professor of Pathology at University College. In 1911 he was the first recipient of the Lannelongue International Prize in Surgery. Elected when quite young to the Royal Society, he was a Royal Medallist of the Society and a Foreign Associate of academies and scientific bodies all over Europe. From 1897 to 1906 he was a Direct Representative on the General Medical Council, he was the first chairman of the Representative Meeting of the British Medical Association, a body called into existence at the reconstitution of the Association, he was a candidate for Parliament in the Liberal interest, standing especially on temperance and women's suffrage lines.

Such is the brief outline of Victor Horsley's life, and in every indicated direction he became a leader in thought and in action. By the end of the "eighties," and whilst still about the age of 30, he had gained for himself an extraordinary position owing to his original work in various directions on ground common to physiology and pathology. As secretary to the Myxœdema Commission, whilst Ord and others supplied clinical material, Horsley collected information from Switzerland, and furnished the needed proof by removal of the thyroid gland from monkeys. When he became superintendent of the Brown Institution he was called upon to investigate the widespread occurrence of rabies and hydrophobia. He had learned under Pasteur in Paris to recognise rabies in the material sent to the institution from various animals in addition to dogs, such as cats, foxes, horses, rabbits, and the deer in Richmond Park. There had been much confusion as to the signs of the disease. On the one hand there was a mare which, after being bitten on the muzzle by a dog, kicked the stall to pieces in violent excitement, and on the other hand the so-called "dumb rabies," the rapidly ascending spinal and bulbar paralysis from which Horsley's laboratory attendant died. Horsley's investigations into rabies formed the scientific basis of the Muzzling and Quarantining of Imports Orders which stamped out the disease, in accordance with his published prediction. He surrounded himself at the Brown Institution with a number of workers, all of whom shared his enthusiasm. For instance, L C Wooldridge was engaged on that fundamental subject in physiological chemistry—blood

coagulation—and, aided by Horsley's suggestions, he perfected a most striking experimental demonstration of the effect of normal saline infusions. From this arose the use of normal salt solution in this country, previously it had been entirely unknown in surgical practice. The sudden death of Wooldridge deeply affected Horsley, he connected it with other cases in which cardiac and visual disturbances had been attributed to tobacco, and the event intensified his antipathy to smoking.

In many investigations Horsley was the active leader and in many he was an effective partner. He mapped out with O E Beevor the areas on the brain of the rhesus and allied monkeys. When they were able to obtain anthropoid apes they demonstrated the arrangement of the sensor motor areas in front of the fissure of Rolando, and confirmed the existence of the so-called "silent" areas both points having already been brought under Horsley's notice in man. A series of experiments on the spinal cord including the production of degeneration along tracts, and the demonstration of spinal cord currents were performed in conjunction with Professor Goltz at Oxford. The results of their work were published in the Croonian lecture at the Royal Society in 1891.

Concurrently with his work at the Brown Institution Horsley was in charge of the pathological laboratory at University College, where he was ably seconded by Robert Boyce. The Syllabus of Lectures on General Pathology which they drew up was exhaustive, the one thing lacking was an audience. The medical student was concerned only with the requirements of his examination, teaching was then confined to pathological anatomy and histology, which had its focus in the old Pathological Society, and Horsley and Boyce were before their time. Horsley became one of the principal originators of the Pathological Club which in its turn anticipated the wider scope of the present Pathological Section of the Royal Society of Medicine, including its laboratory meetings. Everybody recognises nowadays the importance of chemistry but there was much criticism when Horsley's influence enabled a department in chemical pathology to be set up alongside his laboratory. Press of work soon forced him to give up both the Brown Institution and the Pathological Laboratory at University College, but he continued to carry on original investigations. Perhaps the two to which he devoted most work over a prolonged period, and in which difficulties and obscurities have presented hitherto insuperable obstacles, were those relating on the one hand to epilepsy, and on the other hand to intracranial tension resulting in particular from bullet wounds. Whatever he may have published on these subjects must represent but a fraction of the time, labour, and thought he devoted to them.

Horsley in all his experiments and researches had a practical aim in view, he lived and died in the practice of surgery. He served at University College Hospital in the various posts up to that of surgeon, but it is as surgeon to the National Hospital for the Paralysed and Epileptic that he will be chiefly known. Before him the surgery practised there had been limited to the haphazard uncritical performance of tenotomy which Stromeyer and Dieffenbach had popularised in the "forties" of last century. Horsley's three cases of brain surgery, read at the British Medical Association Meeting in 1886, marked the commencement of a phase of notable activity. His experiments in connexion with myxœdema started him on the surgery of the thyroid gland, and the nervous disturbances connected with that gland linked it with cerebro spinal surgery. Moreover, arising out of the myxœdema inquiry he made experiments on the removal of the pituitary gland in animals, subsequently he began to operate for pituitary tumours. The remarkably successful operation in which he removed a tumour which had been diagnosed by Gowers as compressing the spinal cord forms a permanent landmark in the history of surgery. He had to begin operating at the National Hospital without the provision of an operating theatre. Just as Spencer Wells did his first ovariectomy at the Samaritan Hospital, so Horsley started to expose the roots of the fifth nerve and the Gasserian ganglion in the corner of a ward shut off by screens. The wonderful physiological and pathological knowledge possessed by Horsley enabled him to achieve many extraordinary successes, but he met also with partial success, as well as with failure, and the records of the work which he did are neither full nor satisfactory. He commenced quite early to

sketch out a systematic work on brain surgery, but whilst he published a number of remarkable contributions on various sections of his work the systematic book has not appeared. It would be a great contribution to surgical knowledge if to the publication of his long list of successes there might also be added details of the cases in which his best efforts failed to achieve their object.

A significant feature of Horsley's experimental work in neurology was his explicit belief that experience in laboratory research is of direct value to the clinician, and especially to the surgeon. His own experimental investigations were characteristically those of a clinician seeking in the laboratory

to obtain light on the symptoms seen in the clinique. His theme was therefore practically always the "localisation" problem in one or another of its forms the "localising" of centres or the "localising" of conducting tracts. Thus, the original results of Ferrier on the functional topography of the cortex of the cerebrum were minutely reworked over, and a number of important details added. The upward conduction lines in the spinal cord were reinvestigated and attempts made at better quantitative evaluation of the crossed and uncrossed effects. The region of the thalamus was carefully explored with interesting results. The subject of cerebellar function as far as it can be studied by electrical stimulation was laboriously re-examined and new data contributed. All this work was done in collaboration now with one colleague now with another, and that fact exemplifies a mental trait characterising Horsley in other of his activities as well—namely in tense striving

after cooperative effort. In his collaboration with others in research he himself usually suggested the immediate aim towards which the investigation should be directed, and the elaboration of the method employed would lie with his collaborator. These partnerships were many and brought much of neurological value to light. Contact with him in the laboratory was always an incentive to effort. His early activity as an investigator by experiment and his fearless public endorsement of the rights of such inquiry brought on him the special opprobrium of the antivivisectionists. He contributed largely to the public refutation of the misstatements of these opponents. Among all the varied social

interests of his later life this keen championship for the rights of those who engage in inquiry by vivisection remained ever as active as it had been at the beginning of his career.

The following has been sent to us by a pupil of Horsley who later became a colleague. It repeats details that we have already mentioned in presenting a very complete, if brief, picture of Horsley's neurological work. "If we are to judge of a man's pre-eminence by the reputation his work obtains both at home and in continental and foreign schools of medicine, few have equalled and none surpassed that which was universally acknowledged as having been worthily earned by Sir Victor Horsley. As a cerebral physiologist and

anatomist he was in the very front rank of experimental workers. The passion which he showed while yet a surgical registrar at University College Hospital for this variety of research never was dimmed through the busy years of a very large surgical practice. Taking up with characteristic energy and enthusiasm the lines of research initiated in this country by Sir David Ferrier, he probed ever further into the intricacies of cerebral and cerebro-spinal function. The Philosophical Transactions and the Proceedings of the Royal Society, the *Journal of Physiology*, and *Brain* more particularly of the 'eighties' and 'nineties' of last century, contain a series of papers which, when judged merely by the quantity of output seem a tremendous accomplishment for a young man, but when their originality and quality are also considered they will be admitted to constitute a record that is all but unique. By himself, or in collaboration with Sir Edward Schäfer the late

SIR VICTOR HORSLEY, F.R.S.
COLONEL (TEMP.) ARMY MEDICAL SERVICE.

Professor Gatch, Sir Felix Semon, and others, he made enduring contributions to our knowledge of the functions of the brain and spinal cord. Perhaps his best work in this respect was done in association with the late Dr Charles Beever. This was an ideal combination, the enthusiasm and rapidity of work of the one had a valuable counterpoise in the patience, caution and critical hesitancy of the other. Their joint work on the connexion of the cortex with the lower centres on the electrical excitation of the cortex and internal capsule of the orang outang on the internal capsular fibres of the bonnet monkey, on the

motor cortex of the monkey, on the centres for face, mouth, throat, and larynx in the ape, &c., has long ere this been acknowledged as classical. Horsley would not allow the exigencies of his surgical work to interfere with his experimental investigations. He organised a laboratory of experimental neurology at University College, and there he was always to be found on certain afternoons in the week tackling fresh problems with undiminished ardour, as the pages of *Brain* testify. None who have ever worked there under his ægis are likely to forget his infectious keenness and his unequalled generosity. All that he asked was that men who came there should be workers, and they did come, in an unfauling stream, from home, from the colonies, from America, Germany, Poland, France, and elsewhere. It was a matter of indifference to him whether their researches were published with or without his expressed collaboration, all recognised that he was the leading spirit in the international coterie that laboured in that odd shaped and out-of-the-way room which to many of the younger generation of neurologists at home and abroad was a veritable Mecca. Brilliant and enduring as his reputation is certain to be as an experimentalist, his world wide fame rests undoubtedly on his superlative eminence as a neurological surgeon. The surgery of intracranial and spinal tumours was a *terra incognita* when Horsley began, in the 'eighties' of last century to explore where others had been afraid to tread. Fortified by his experimental knowledge, and with a sureness of touch acquired in a similar way, he did not hesitate to tackle any form of cerebral or cerebellar case, as an early paper of his in the *British Medical Journal* for 1887 will show. This article was written to demonstrate, among other points, the 'details and safety of his methods,' words which must appear a little strange to day, when cerebral surgery is undertaken almost as a routine. In 1888 he successfully removed a spinal tumour by operation in a case under the care of the late Sir William Gowers. This was the first time the operation had been performed, and it was an epoch marking event. The full record of the case is in the *Medico-Chirurgical Transactions* for 1888, and is well worth perusal. Thenceforward Sir Victor Horsley's position as a bold and skilful neurological surgeon was supreme. At the International Medical Congress held at Berlin in 1890 his communication on the surgery of the central nervous system was hailed with acclamation. The tribute of the foreigner was voiced in Professor Oppenheim's 'Lehrbuch der Nervenkrankheiten' when he declared that 'this celebrated neurologist and surgeon has since then remained the master of his subject, and he may well be proud of his great experience and success.' Not content with his attainments, Horsley laboured continually to improve his technique in intracranial work, witness the address on surgery given at the Toronto meeting of the British Medical Association in 1908. The prime factor in his astonishingly successful results was the speed with which he operated. No one could handle his instruments so dexterously as he did himself, though his methods have been copied and modified far and wide. While scientists made their way to his laboratory for his experimental investigations, distinguished clinicians came to Queen square to see him operate. It was no uncommon sight to see there such visitors as Kocher, Babiniski, de Martel, Picque, and others that might be mentioned. His audience in the operating theatre at the time of the International Medical Congress of 1913 was a particularly brilliant one. Horsley's results in extirpation of the Gasserian ganglion for trigeminal neuralgia were particularly good, and he had operated on hypophyseal tumours half a-dozen times or more by the subtemporal route before any other surgeon had begun to record similar essays. He was facile princeps in neurological surgery, a prince of brain surgeons. With characteristic independence and, one may almost say, impatience, he made his own diagnoses and almost say, his own ideas in regard to treatment in a carried out his own ideas in regard to treatment in a way that sometimes brought him into conflict with his medical colleagues. But he was ever a fighter, and his self confidence was widely based on his unequalled experience. Neurology as a science owes its established position to the labours of those mighty pioneers whose names are familiar to all the profession. Among them the name of Sir Victor Horsley is inferior to none in actual international fame, it is that also of a man who in versatility of accomplishment and in combination of theoretical and practical attainment was unequalled by any.

An officer who served with him in Egypt writes of the last phases of his strenuous career in these words: "Victor Horsley's death in Mesopotamia is one of the tragedies of the war. I had the honour of being attached to the general hospital in which he at first was in charge of the surgical section. That a man of his eminence in the profession should have consented to accept such a post was a proof, if any were needed, of his intense desire to do everything that lay in his power to serve his country. From the very first his energy and keenness was an example to us all. Soon after his arrival in Egypt he was given an appointment more in keeping with his professional position and was made consulting surgeon to the Forces. Before this, however, he had done an immense amount of valuable work in assisting to organise the surgical side of the base hospital to which he was originally attached. As a consulting surgeon he did splendid work, he devoted with unsparing zeal both time and energy to finding out and correcting, as far as lay in his power any defects of equipment or mistakes in organisation in the hospitals, and in the early days in Egypt there were many of these. He was always ready to help with his advice and example those of us who asked him to do so, and in the midst of the most trying circumstances he never lost his cheerfulness or good temper. In spite of all the calls upon him he found time to carry out some original work in connexion with the infection of head wounds, and it was entirely owing to his teaching and example that the results of the operative treatment of these injuries, at any rate in one of the hospitals, were so extremely good. His energy and devotion to his work was the more striking because it was obvious that the atmosphere of a military hospital was not very congenial to him and when we remember his force of character and independence this is not to be wondered at. The amount of work he got through in Egypt undoubtedly tried his strength, and he could not be persuaded to rest to the extent that was really necessary, especially in the hot weather. A tour of inspection which he paid to the Peninsula did him good in this respect, but the many muddles and deficiencies which he found there must have had a depressing effect upon his spirits. He volunteered for duty in Mesopotamia without any thought for himself, and I am sure that he went there in the hope that he might be able to do something to remedy the defects in the medical arrangements which are now so notorious. If he expended as I am sure he did all his strength and energy on this work, it is little wonder that he should have succumbed to the effects of that most trying climate. Victor Horsley was a most charming personality and he was a great favourite in our mess. His death leaves a blank in the branch of surgery, which his genius had played so large a part in founding, that at the present there is no one fitted to fill it." Great as were the services rendered by the late Sir Victor Horsley to physiology and surgery, he had titles to fame outside his professional work. For some years prior to the war he had devoted much time and energy to politics, taking an active part in elections, and standing for the University of London at the last general election. In politics he was an advanced Liberal and democrat. Free Trade the great Budget of 1909, the removal of the undue influence of the House of Lords on legislation all found in him a vigorous and eloquent champion. Perhaps to the outside world he was best known as a most ardent advocate of the cause of temperance, basing his support not on mere general grounds but on scientific reasoning, to which his distinguished professional career added very great weight. He also embraced the cause of women's suffrage with all the ardour of a chivalrous temperament. Had he lived, however he would probably not have made a successful politician, for he understood very little of the art of compromise which is more essential to success in English than in continental politics. His constant employment of the deductive method of reasoning, perhaps the outcome of his scientific training, was peculiarly unsuitable to politics, and especially to the politics of this country. He could not have subscribed to the dictum of so staunch a reformer as Macaulay that you should never "remove an anomaly simply because it was an anomaly." Horsley's logical mind was out against all anomalies. Like many men of advanced views, he was inclined to think that very much of the evil in the world might be set right by a few drastic measures. He did not possess a profound knowledge of

man nature, and was not interested in trying to understand why men think as they do think, consequently he often led to appreciate the views of his opponents and was finally led to suppose that they were necessarily perverse and obstinate people. With regard to the medical profession he seems to have felt that somehow the State did not know how to make use of the knowledge possessed by such a large body of highly educated and scientifically trained men. Horsley died full of plans for the future, but with a past wonderful accomplishment. He died for his country, leaving taken upon himself a splendid task for which his physique was not wholly fitted, and he will be sincerely mourned by countless friends, pupils, colleagues, and admirers. He had many differences of opinion with many of them, and sometimes they were violent ones, for Horsley was uncompromising, but all such feelings will be merged in one of deep and sincere regret that Victor Horsley should be gone from us.

Sir Victor Horsley married in 1887 Eldred, third daughter of Sir Frederick Bramwell, Bart. by whom he had two sons and one daughter. To Lady Horsley and her family the deepest sympathy will be extended in their irreparable loss.

WALTER WILLIAM HUNT TATE, M.D. LOND.,
F.R.C.P. LOND.,

OBSTETRIC PHYSICIAN TO ST THOMAS'S HOSPITAL.

Walter William Hunt Tate was born on Dec. 18th, 1865, his father, George Tate, being a practitioner in the north of London. He received his early education at University College School, joined University College as a medical student, and finished his clinical work at University College Hospital. He won early recognition from his teachers as a capable and earnest student and held the resident posts at the hospital of house physician, house surgeon and obstetric assistant. He was afterwards elected resident medical officer and performed the duties of this important post with great success. On the termination of this appointment he had intended going into general practice in the Hampstead neighbourhood, but the post of obstetric tutor and registrar at St Thomas's Hospital being created he applied for the post and was elected.

Though appointed as tutor and registrar, Tate was from the first for all practical purposes, assistant obstetric physician, for Dr. Cory, who held that post, was in indifferent health. Dr. Cullingworth, the senior obstetric physician, had a high standard by which he judged men, and that Tate at once obtained his confidence to the full was a tribute to the self-reliance and power which had enabled so young a man to make the most of his unusually favourable opportunity. Dr. Cullingworth entrusted him more and more with a share of the ward work, and relied on him for relief from night emergency work and for holiday duty. The only real difference made by his appointment in 1896 as assistant physician on Dr. Cory's resignation was that he then began regular clinical teaching in the out-patient department in addition to acting as Dr. Cullingworth's assistant and deputy.

It is not however as a teacher in the out-patient room that Tate will be remembered by the St Thomas's men of the past 20 years, but for his work and teaching in Adelaide Ward. His term in the out-patient's was short—barely five years—and during that time the work of the department increased rapidly and the accommodation for patients was enlarged from 20 to 28 beds, so that Dr. Cullingworth, whose health was far from good, left him an increasingly active share in the ward work. In 1901 he became full physician with charge of three-quarters of the beds. Dr. Cullingworth retaining one quarter only, and this continued till Dr. Cullingworth's final retirement in 1904, after which Tate took sole charge.

As a teacher it was the clinical side of the work that appealed to him, and chiefly gynecology. Midwifery never attracted him. He held no appointment at a lying-in hospital and his supervision of the outdoor maternity district was not of long duration and scarcely gave scope enough to distract his interest from the large share in the gynecological work that fell to him. He had excellent clinical insight and came rapidly to a clear opinion on his cases and it was this very faculty of quick decision that attracted students and was an important factor in his success in practice. In addition he was a delightful operator to watch, and

had marked manipulative skill and was intensely interested in all difficult surgical problems that arose in the course of his work—all of which appealed strongly to the students. The amount of hospital work he got through was always a marvel to his house officers and dressers, as well as to those who knew what a busy private practice he had. His teaching experience naturally led to his becoming an examiner and he acted for four years at the Apothecaries' Hall, for five years at the Conjoint Board and at the time of his last illness was serving as examiner at the University of Cambridge.

He was never a prolific writer, though he was a frequent exhibitor of specimens and recorder of cases at the Obstetrical Society and later at the Obstetrical Section of the Royal Society of Medicine. Pathology interested him only so far as it helped in diagnosis and treatment, and his writings reflect closely his bent towards the clinical side. One of his early papers was on "Three Cases of Pyometra Complicating Cancer of the Cervix Uteri," published in the *Obstetrical Transactions* for 1897. Another paper read in 1904 on "Three Cases of Intestinal Obstruction following Operations for Fibroid Tumour of the Uterus, with special reference to the choice of operation," in which he advocated total hysterectomy rather than supravaginal amputation, gave rise to an interesting discussion. Many short communications and descriptions of specimens and cases are to be found in the *Obstetrical Transactions*. In the *St Thomas's Hospital Reports* are several papers from his pen, among them one on the Clinical Aspects of Tubal Gestation in the Early Months, and another on Cancer of the Uterus containing clinical observations on 50 cases treated by vaginal hysterectomy, an operation in which he had considerable experience and much success, though latterly he gave it up for the abdominal route. Other papers on gynecological subjects may be found in the *Journal of Obstetrics and Gynecology of the British Empire the Practitioner*, and the weekly medical press, and doubtless, had he been spared to review his extensive hospital and private practice, he might have left more of his valuable experiences.

Tate took a prominent part in the work of the old Obstetrical Society and of the Obstetrical Section of the Royal Society of Medicine. He was first elected to the council in 1895 served as an examiner for midwives on the old examining board in 1898-99 filled the office of secretary in the years 1911 to 1913 and at the time of his death had just been elected President of the Obstetrical Section of the Royal Society of Medicine for the ensuing year.

He married in 1896 the widow of the late Dr. Anthony Dalzell, who survives him, there were no children of the marriage.

THE ASSOCIATION OF INFANT WELFARE AND MATERNITY CENTRES.—The fifth annual conference of this society was held last week in Bristol. Dr. D. S. Davies, the medical officer of health of the city, presided at the opening and welcomed the delegates. Dr. Eric Pritchard, the chairman of the National Association, in the course of his speech, stated that specialists were not as suitable for the work as well-informed nurses and health visitors.

PRESIDENCY OF THE ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—Earlier in the year the Royal College of Physicians of Ireland appointed a committee to consider the method of electing the President of the College. The College has now received and considered the report of the committee, and at its last meeting passed a series of by-laws designed to introduce considerable modifications in the mode of election. For more than 200 years it has been the custom in the College for the various officers to elect a President among the Fellows of the College resident in Dublin in order of seniority. Since 1830 it has been the custom for the President to hold office for two years. This method of election had much to recommend it when the number of Fellows was small, but in recent years the presidency tended to lose its dignity since it became a prize automatically awarded for mere longevity. The College has now decided to make a real choice effective in electing the President. In September of each year a ballot will be held for the selection of a panel of three Fellows as candidates for the presidency. On the first Friday of October the College will, by a further ballot, select one of the three for nomination as President and on St. Luke's day the name of the fellow so nominated will be submitted for formal election. In the ordinary course the President will hold office for three years, but provision is made for a more frequent change if the College should so decide.

Correspondence.

THE EFFECT OF FERRIVINE AND INTRAMINE ON SYPHILIS

To the Editor of THE LANCET

SIR,—Mr J E R McDonagh states in your issue of July 15th, in a letter with this heading, that I should not have made my objections to his theoretical views if I had read his work. My delay in answering his letters is mainly due to the careful attention that I have given to his Hunterian Lectures, "Links in a Chain of Research on Syphilis (Oxidation and Reduction)," delivered in March, 1916. This is a book to which he specially refers, and we may suppose that it gives his latest conclusions. The references in the following lines apply to pages in this work. I can only say that my mystification is greater than ever. When description is given of the various well known phenomena applying to the subject the statements are perfectly intelligible and correct. It is only when he proceeds to give his own ideas that what appear to be the most extraordinary statements are made. We might apply to the book as a whole the saying that "What is true is not new, and what is new is not true." Now, the difficulty that I feel is that, although quotations might be made from nearly every page whose incorrectness would be obvious to the physical chemist at a glance, yet it is not to be expected that readers of this journal would have had the opportunity or necessity to acquire a similar knowledge. They have, indeed, so much other matter to take account of which is of vital importance in their work. I must therefore limit myself to a few of the more obvious cases.

The basis of Mr McDonagh's theories lies in what he calls "lipoid globulin molecules" or particles their varying distribution in the blood of normal and syphilitic patients and their presence in large amount in the parasites themselves. These molecules are supposed to constitute an "oxidase-reducase system," and the whole edifice really rests upon this hypothesis or "fact." I am not prepared to deny the existence in the blood or elsewhere of such adsorption compounds, indeed, it is very probable. But what is the evidence that they are endowed with the properties of oxidising or reducing enzymes? When I used the expression "selected," to which Mr McDonagh takes so much objection I had in my mind the possibility that the phenomena interpreted as due to oxidation and reduction might turn out to be at least as readily explicable on other hypotheses, especially as the complexity and obscurity of oxidation in the living organism so easily leads to misunderstanding. Doubtless I did not make use of quite the correct words. My consideration of the small amount of experimental basis this view has confirms me in my opinion. The evidence amounts to the presence of unsaturated carbon atoms in the lipoids of the complex and to certain reactions to dyes. As far as the former is concerned, the particles seem to be possessed of some degree of reducing power, but not a great one. Curiously, the reaction to osmic acid was not tested. But even a considerable degree of reducing power does not imply catalytic activity as a reduction enzyme or reducase. Oleic acid is not regarded as a reducase. In the paper by McDonagh and Mackenzie-Wallis it is expressly stated that no evidence was to be found of the presence of an oxidase or a peroxidase in the particles. Nevertheless, on p 19 of the "Links" it is said that peroxides and peroxidases form part of the system, the two together forming an oxidase. As regards the behaviour to dyes, Unna's view of the definite relation of staining to oxygen places in the cell is accepted, notwithstanding that it has clearly been shown to be false by Drury. The adsorption of dyes is quite as complete in the absence of oxygen, active or molecular, as in its presence. I do not admit that processes of adsorption in the living organism are totally different from all other processes, nor that the case of charcoal and carbon dioxide is beside the point. When the statement is made that

adsorption in *corpore* differs from other forms, we must remember that staining *in vivo* is understood by McDonagh and Mackenzie Wallis as that of dried films. Moreover alcoholic solutions are recommended for use. Certain of the staining reactions given as proof of reducing properties are clearly connected with electrical charge, but the explanation of this error will be seen immediately.

After having read the greater part of the book, it dawned upon me that many of the misconceptions in it are due to the fact that the author regards as identical in nature not only the OH groups in organic compounds and hydroxyl ions (p 22), but also hydrogen peroxide (p 139). This latter represented as OH + OH (p 22). In another place (p 1) the OH group is considered to be a reducing agent. The confusions lead to the putting forward of some rather astonishing chemical equations, such as the following—

The hydrogen ion is called here, by the author, "active hydrogen," just as in other places (pp 139 and 179) the oxygen ion (O⁻), which is so rarely met with and even then in negligible quantity, is regarded as identical with active oxygen. It is scarcely necessary to point out that the "active hydrogen" and "active oxygen" which are concerned with reduction and oxidation processes not the ion produced by electrolytic dissociation, although on p 1 Mr McDonagh says that "active hydrogen is a cation and refers to the negative charge that active oxygen possesses." What these forms of oxygen and hydrogen really are is not known. All that can be said as yet is that in some way their chemical potential is raised by the supply of energy, so that they are able to oxidise or reduce substances which the ordinary forms of these elements are unable to act upon. Active oxygen is not necessary for all oxidations, contrary to the statement on p 171. Atmospheric oxygen has a sufficiently high oxidation potential to combine with pyrogallol, as every photographer knows. Dilute nitric acid is rich in hydrogen ions but has no reducing properties. Ions must be looked upon as chemical compounds of atoms with electrical charges and therefore of a different chemical nature from the atoms themselves. The globulin component of the "lipoid globulin particles" is, of course, as an amphoteric electrolyte, capable, at least potentially, of affording either hydrogen or hydroxyl ions, but this is a totally different matter from acting as a reducing or oxidising system. For this latter statement, indeed, I can find no reference given to any experiments of a satisfactory nature. The majority of the original statements in Mr McDonagh's book are, in fact, given without experimental evidence or reference to experiments made. While many of these statements are clearly due to misconception, others may possibly be true, but they are at present quite incapable of experimental test since the means of doing so fails us.

Other difficulties in the way of a clear comprehension of Mr McDonagh's views are due to his use of words in a sense which is not only different from that generally understood, but in some cases is unintelligible. I will mention three. Permeability is used by physiologists to refer to the properties of the cell membrane in connexion with the admission of substances to the interior of the cell, but Mr McDonagh uses it in application to molecules (pp 63 and 76). The permeability of molecules is said to be increased by richness in carboxyl groups (p 117) on which grounds I am unable to make out, in fact, I do not know what the expression means. Electrolytic dissociation is spoken of (pp 45, 62 and 101) as being something that happens to ions whereas ions are generally supposed to be the results of it. The word "ionised," in the case of electrolytes in solution means the same thing, but Mr McDonagh uses it in a sense which puzzled me greatly until I realised that a protein which possesses ions adsorbed on its surface is called by him "ionised" (p 101). Adsorption should only be used to refer to condensation at interfaces between phases and is a function of surfaces as such. But Mr McDonagh evidently understands something different although I cannot make out what it is. This is shown by his assertion that active oxygen is necessary (pp 46 and 107) acting as catalyst (p 52). I accept his explanation with regard to the effect of increased size of particles but in the "Links" the fact of increased size and increased adsorptive capacity are so frequently referred to without mention of increased

umber that I think my mistake was justified. On p 35, moreover, it is stated that in order to prove that the adsorptive capacity of the lipid protein particles is greater in syphilis it is only necessary to show that these particles are larger. In other places "adsorption" is merely chemical combination, a trivalent metal is said to "adsorb" three atoms of hydroxyl ion" (p 114), and in amino-thioenzyme the sulphur is said to be in a "more powerfully adsorbed state" when in the ortho-position as regards the amino-group (p 136). In this connexion it is curious to note that Mr McDonagh prides himself on not introducing new terms. It would surely have been preferable to do so rather than to introduce confusion by using well known ones in ways peculiar to himself.

I pass on to the new remedies introduced. I am, of course, incompetent to discuss their clinical value, which is naturally independent of theories as to their mode of action. But I feel convinced that great mischief will result, both to the theory and the practice of therapeutics if Mr McDonagh's views are accepted on such slender evidence as that he gives. Although the importance of the subject may reasonably be held to warrant the length to which this letter has already extended, I must apologise for the space taken up. However we may disagree with the interpretation put by Ehrlich in his discoveries, there can be no doubt that many valuable compounds and methods have been introduced by him, and that his work has led to great advances in science. Mr McDonagh's attack on Ehrlich (p 120) because he patented salvarsan, although he was not engaged in medical practice, is particularly ungenerous from a man who is engaged in practice, but nevertheless allows the advertisements now appearing in the medical press. As to the suggestion on p 122 that the preparation of a substitute for salvarsan ought to have been handed over to one or more medical men, I should like to know what medical man, with the exception of Mr McDonagh himself, would have been willing to undertake the duty. A remark of an astonishing nature to a chemist is that on p 121, where it is said that two substances to be "absolutely chemically the same, it is necessary that they should be prepared in exactly the same way." So that glycine prepared by the hydrolysis of gelatin is not the same substance as when prepared by the action of ammonia on chloroacetic acid and "ferrivine" is only to be accepted as such when prepared under Mr McDonagh's direction. "Intramine" is a representative of the large class of compounds which contain sulphur in organic combination. They certainly possess as a rule reducing properties, and intramine is used by Mr McDonagh for this reason. But, as we have seen, his "oxidase reductase" theory has no real foundation. It is an interesting example of the mode of reasoning adopted like the case given on p 150 where two injections of intramine are described as being followed by extraordinary improvement while a third dose resulted in a state worse than the original one. Galyl, a true organic compound of arsenic, was then given with remarkably beneficial effects, practically amounting to cure. This is said to be a proof of the theory of oxidation and reduction in that the arsenic compound as an oxidative agent was made effective by the previous administration of a reducing agent. The natural conclusion to be drawn is surely that intramine is useless while galyl is a valuable remedy. We cannot in the present state of science give any explanation as to why certain metals have such powerfully toxic effects while others are harmless, but it may safely be said that it is not a question of valency. The nature of organo-metallic compounds does not seem to be appreciated by Mr McDonagh. The metal must be in organic combination, in direct union with carbon atoms. Such compounds are not subject to electrolytic dissociation with production of metallic ions, therefore the valency at all events in the sense used on p 130 as precipitating power does not concern us. If this were so pentavalent arsenic would be more active than trivalent whereas according to the statements on p 130 it is less so. We naturally ask what is the particular value of this class of compounds? It cannot be stated exactly but it seems probable that the function of the organic part of the molecule is to facilitate passage through the cell membrane so that the metal may be presented to sensitive constituents in the cell without being in the form of anion. The presence of amino-groups favours this permeability. Aniline for example is toxic because it enters the cell, sulphathiazole does not enter and is innocuous. There is I think some

confusion introduced by the use of the terms "toxic" and "non toxic" with regard to remedies. What we want, surely, is something which is toxic to the parasite and non-toxic to the patient, but we are unfortunately still in the dark as to what are the chemical and physical properties required. I fear that Mr McDonagh's theories will not help us much.

Now iron in true organic combination is remarkably inactive as we see in hæmoglobin. But do "ferrivine" and "aluvine" contain the metals in organic combination? The names given on pp 146 and 147, "tri para amino-ferric benzene sulphonate," and so on, suggest that iron is in similar combination with the benzene nucleus as is arsenic in salvarsan, but when the formula is examined it is seen to be neither more nor less than the iron salt of sulphanilic acid and no organic compound of iron at all. If the chemical name is given it ought to be ferric para amino-sulphonate or, more simply, ferric sulphanilate. It is extremely unlikely that such a compound would have any special action different from an ordinary ferric salt. The name manganese sulphanilate is used on p 144, so that I do not suggest that the misleading nomenclature is intended to deceive but content myself with calling attention to it. If it were true, as Mr McDonagh states (p 167), that electrolytic dissociation is necessary for therapeutic action, organic arsenic compounds would be devoid of activity.

The "Links, &c." has the effect upon me of a physico-chemical nightmare. On p 191 we read "There is probably only one protein (in the resisting substance)—albumin, this by increasing the number of its amino-groups becomes globulin, by increasing its carboxyl groups it becomes lipid globulin. An increase of carboxyl groups results not only in making the reducing action greater, but also in increasing the size of the particle and rendering it more permeable, which results in that particle becoming less ionised." No wonder that, as we are told, the cell looks upon it as a foreign body after these astonishing transformations and that malignant disease results, as we read further on.

Mr McDonagh does me the honour of stating his indebtedness to my "General Physiology." I trust that no more results of a similar kind will be laid to its charge, or I shall have to regret its publication. In answer to Mr McDonagh's charge that I have not studied his research work nor repeated his experiments on serum I can only say that if he will give references to where the experimental proofs of his assertions are to be found I shall be happy to look them up. As to experiments on serum, I have neither the time nor the necessary acquaintance with the special methods to be able to repeat them. I have, in the course of the above remarks, given all the evidence I can find that the lipid globulin is an oxidase reductase system and pointed out that it is unconvincing, and this is the foundation of his elaborate theory. It is supposed to explain not only dyeing and staining and chemo therapy, but also immunity and anaphylaxis. It is stated to follow "simply and logically" from "ascertained facts" and to be "deduced from established chemical and physical facts" (p 199). Let me give an example of what are regarded as facts. On p 178 we read "Fever means an increase of hydroxyl ion concentration and therefore more oxygen. Reduction is only a means of increasing oxidation, as it forms the peroxide necessary for the oxidase system." No reference is given to experimental evidence, yet the next sentence begins "In view of these facts," &c. The chemical equation given above is also a "fact." As to logical deduction, take the following (footnote on p 152) —

Intramine injected into the urethra causes a great increase of soluble phosphates and carbonate in the urine. — These are the salts which regulate the normal hydrogen ion concentration of the external phase therefore this observation proves beyond doubt that intramine acts on the oxidase-reductase system.

Mr McDonagh complains that I represent him as holding that lipid globulin acts at the same time as an oxidase and a reductase. On p 112 certain granules in the choroid plexus are stated to synthesise indophenol owing to the presence of active oxygen, and in the next sentence they are stated to have a reducing action due to the presence of active hydrogen. On p 197 reference is made to the "fact" "that the adsorptive power of the active oxygen in the oxidase-reductase system is more marked than that of the active hydrogen" and on p 198 to "those lipid globulin particles which are richer in active hydrogen than in active

oxygen." If any meaning is to be attached to these words they surely mean that active oxygen and active hydrogen are present together.

To sum up, I hold that no proof has been given that the lipid globulin particles form an oxidase reductase system, nor that oxidation and reduction play any part in the mode of action of the antisyphilitic remedies in question. Mr McDonagh must find another foundation for his theories or give better evidence for that which he puts forward.

I am, Sir, yours faithfully,

University College, London, July 18th 1916 W M BAYLISS

THE CARDIAC DISABILITIES OF SOLDIERS ON ACTIVE SERVICE

To the Editor of THE LANCET

SIR,—I must confess to a feeling of bewilderment not unminged with dismay at reading the criteria of Captain John Parkinson in his inquiry into the cardiac disabilities of soldiers on active service in your issue of July 22nd. If, indeed, we are to accept his sixth conclusion that the absence of abnormal physical signs in the heart of a soldier should not prevent his discharge from the Army if, under training or on active service he shows breathlessness or precordial pain whenever he undergoes exertion well borne by his fellows, then inasmuch as during the past 18 months some 1400 men who would correspond exactly to this description have been sent to me for an opinion and have invariably been returned to full duty, the amount of irreparable damage I would seem to have caused in this time may well be described as overwhelming!

If I have read his impressions correctly, Captain Parkinson is disposed to regard the symptoms of precordial pain and breathlessness on exertion as of not merely positive but supreme value, since he states that if such symptoms bear no relation to increase of pulse-rate on exertion, the latter is therefore valueless in judging the functional efficiency of the heart (Conclusion 4). Now, inasmuch as precordial pain is entirely a subjective sensation, as a scientific standard it must surely be disregarded as of little, if any, worth. The importance to be attached to breathlessness on exertion is again, in my opinion, exceedingly slight. The breathlessness of which such patients complain—men without abnormal physical signs—is not by any means a true dyspnoea. It is shallow breathing, what is often termed lazy breathing, in fact a panting rather than an attempt at adequate respiration. It can be improved out of all recognition by the imposition of strenuous breathing exercises and demands a species of physical discipline to which the subject has been hitherto entirely unaccustomed. On the other hand, the reaction of the pulse-rate to violent exercise is an experiment which can be performed with perfect scientific exactness, and why such evidence of the heart's efficiency is not valid I am quite unable to see. The malingering will never have any difficulty in describing precordial pain of all grades of intensity, it is not so very difficult for him to simulate breathlessness by shallow respiration, but it needs some art to adjust his pulse rate so that its return to the normal after exercise is unduly prolonged.

As I have stated, on an average three men per day are sent to me with a history that they cannot do the square or fall out on parade on account of pain in the heart and getting out of breath. I base my criterion of their cardiac efficiency on the rhythm, the size of the heart and the reaction to violent exercise, and in the event of no abnormality being detected in any of these, I have no hesitation in excluding cardiac disease, and recommending such men for full duty whatever their symptoms, some of which will frequently disappear after dental treatment and the remainder by breathing exercises, persuasion, and reassurance. I frequently hear from medical officers to whom such recommendations have been made that the men have trained on without further trouble. Of course, such a description does not apply to all of Captain Parkinson's cases of 'soldier's heart,' some of which are clearly instances of organic cardiac disease. On the other hand, some are very evidently of the type to which I am referring—faint-hearted in the spiritual sense, who have never been able to play games, and tend to give up at the least discomfort upon unaccustomed exertion.

The question is one of great importance from two points of view. The invaliding of a large number of men who with

persuasion might have made efficient soldiers is, of course, a serious loss to the active force. In the second place, the act of boarding out as unfit for military service on the grounds of some cardiac disability is a serious burden on their future life to men to whom such a diagnosis has other meaning than heart disease with the constant danger of sudden death.

I am, Sir, yours faithfully,

ADOLPHE ABRAHAM

Temporary Captain R.A.M.C. Officer in Charge of Medical District
Connaught Hospital Aldershot,
Aldershot, July 22nd 1916

CONDENSER DISCHARGES IN PHYSIOLOGICAL EXPERIMENTS

To the Editor of THE LANCET

SIR,—Dr F. Herniman Johnson writes in your issue of July 15th on the subject of condenser discharges, and urges physiologists to abandon the use of an instrument notoriously incapable of standardisation as the inductive coil. If he will read the numerous papers on electric stimulation which have been published by Nernst, Wel Hoorweg, Professor and Mme. Lapicque, Keith Luc A. V. Hill, and others, he will see that the merits of the condenser discharge have been recognised by physiologists for 15 years or more, and that it is by no means the most instructive or the most easily controlled form of stimulus. Indeed modern theories of stimulation have been arrived at mainly by the use of progressively increasing currents at of constant currents of short duration though it is true the experiments with condensers have contributed materially to the present state of our knowledge. In many experiments it is quite unnecessary to vary the time relations of the discharge, and in this case the break shock of an inductive coil is often the most satisfactory form of stimulus. It is necessary it can be calibrated with very great accuracy. That the ordinary medical coil is incapable of standardisation is scarcely the fault of physiologists.

I am, Sir, yours faithfully,

E. D. ADRIAN, M.B., B.C. Cantab

Farnborough, Hants, July 18th 1916.

THE SHARPENING OF HOLLOW NEEDLES

To the Editor of THE LANCET

SIR,—The following may be of use to your readers who have occasion to use hollow needles very much and have trouble with keeping them in repair. Procure throughout an ironmonger, or from a dealer in the carborundum wares slip No. 89. Sharpen the needle by holding it on a support, such as a cork in a bottle lumen upward, and shank level.

and rubbing it at right angles to the axis of the needle, the round edge of the slip till a hollow ground effect obtained. Then lightly touch the back edges of the needle on the flat of the stone to get rid of the rough edge and obtain a sharp point. This answers excellently for all sizes and natures of hollow needles, from hypodermic sizes to aspirator or pneumothorax instruments. The slips are 1s. 6d. When new they are rather too fierce, and may be dressed by soaking in a fairly viscous oil, such as liquid paraffin, for a few hours. After that they need only a light dressing of oil to make them do their work, and no oil at all for platinum iridium instruments. The sharp edge of

hp is ideal for notching the necks of capsules containing vaccine and serums previous to opening

I am, Sir, yours faithfully,

EDWARD BIGG

ELECTROLYTIC HYPOCHLORITE SOLUTION FOR SURGICAL USE

To the Editor of THE LANCET

SIR,—The credit of discovering that hypochlorite solutions are rendered more permanent by the use of magnesium hydroxide in a state of "gel" is due to Mr F W Alexander,¹ medical officer of health of Poplar

During the past year many experiments have been made, and the following method affords a reliable solution for surgical use. Magnesium chloride ($MgCl_2$, 6 aq) 410 grammes and sodium chloride 325 grammes are dissolved with 1.5 grammes of potassium iodide in 9 litres of water. To this mixture magnesium chloride 20 grammes dissolved in water 500 c.c. and mixed with constant stirring to sodium hydroxide 8 grammes dissolved in 500 c.c. of water is added. The turbid solution of chlorides and iodide with the suspended "gel" of $Mg(OH)_2$ is then electrolysed with a flow of 1 litre per hour under a current of 3 to 5 ampères by means of thin Pt foil electrodes of 8 cm. by 2 cm. area. A permanent solution of hypochlorite yielding 3.5 to 4.5 grammes of available chlorine per litre results. The strength is estimated before sending to the wards by titration with decinormal arsenic solution. Magnesium chloride is obtainable at about 3d per lb, and the current is taken by a shunt from the constant current in use for lighting the hospital. When the alternating current is used a small aluminium and ammoniac phosphate rectifier is interposed. For use the solution is diluted with 3 parts of warm water, and in some cases sodium citrate has been added.

I am, Sir, yours faithfully,

T GODDARD NICHOLSON, B.Sc., M.B. Lond., M.R.C.S.
London Fever Hospital N. July 9th 1916

THE ADDRESS OF MEDICAL PRACTITIONERS SERVING IN THE ARMY

To the Editor of THE LANCET

SIR,—Practitioners now serving in the R.A.M.C. may wish to know what address to give for the next issue of the Medical Directory. As the military address is liable to change and as they may return to civil practice unexpectedly, we recommend the insertion of the home address only.—We are, Sir, your obedient servants,

THE EDITORS OF THE MEDICAL DIRECTORY

7 Great Marlborough-street London, W. July 26th, 1916

¹ THE LANCET Jan 18th 1908, p. 157

Mr T E Gordon, F.R.C.S. Irel, senior surgeon to the Adelaide Hospital has been appointed professor of surgery in Trinity College, Dublin, in succession to Mr E H Taylor. Mr Gordon is not required to perform any duties at Sir Patrick Dun's Hospital.

ISOLATION HOSPITAL FOR PAIGTON (DEVON).—A new isolation hospital is being erected for Paigton at a cost of £3,000. It is nearly completed, and will shortly be opened.

TUBERCULOSIS IN BELFAST.—In reference to the work done at the Tuberculosis Institute Belfast a series of interesting tables have been submitted to the Tuberculosis Committee of the council of the county borough of Belfast by Dr A Trimble, the officer in charge, showing the work done in that department for the year ended March 31st 1916. 1557 pulmonary cases were treated for tuberculosis at the dispensaries and 205 non pulmonary. In the sanatoria and hospitals provided by the council 631 pulmonary and 10 non pulmonary cases were treated, while in sanatoria and hospitals otherwise provided (Union Infirmary and Forster Green Hospital) 363 pulmonary and 1 non pulmonary patients were received. Under the head "Treatment otherwise than in Dispensaries and Sanatoria (including Domiciliary Treatment)" there were 1410 pulmonary and 203 non pulmonary cases. Altogether 4422 cases were treated for various forms of tuberculosis in Belfast during the year ended March 31st, 1916. The population of Belfast is now close upon 400,000.

The War.

THE CASUALTY LIST

THE following names of medical officers appear among the casualties announced since our last issue —

Killed

Captain J D H Acland, R.A.M.C., attached to the Somerset Light Infantry, was a student at St Thomas's Hospital, London, and qualified in 1905. Previously to returning to England to join the R.A.M.C. soon after the outbreak of the war, he was medical officer of the Government Schools at Bulawayo, South Africa.

Captain T Guthrie New Zealand Army Medical Corps.
Captain H G Morris, R.A.M.C. qualified M.B., B.Ch. Oxon in 1914, and shortly afterwards joined the R.A.M.C.
Lieutenant R F T Newbery, R.A.M.C., attached to the Northamptonshire Regiment, qualified M.B., Ch.B. Edin in 1915, and after holding house appointments at the Edinburgh Royal Infirmary for a short period he joined the R.A.M.C. last October.

Previously reported Wounded now reported Killed

Captain G R Heard, R.A.M.C., attached to the Royal Warwick Regiment, was a student at the London Hospital, qualifying in 1909, and was in practice at Devonport prior to joining the R.A.M.C.

Died of Wounds

Captain R W Michell, R.A.M.C. was educated at Cambridge and at St Bartholomew's Hospital, London, qualifying in 1894, and was in practice at Cambridge before joining the R.A.M.C. on the outbreak of war.

Died

Colonel Sir V A H. Horsley, C.B., F.R.S. (see Obituary columns).
Lieutenant S W Burrell, R.A.M.C., was a student at St Bartholomew's Hospital, London, where he gained the Warham prize for surgery, and qualified in 1915.
Surgeon E W Welchman, R.N., was educated at Queen's College, Birmingham, qualifying in 1883, and was in practice at Lichfield before becoming a surgeon in the Admiralty Transport Service.

Wounded

Lieutenant R M Rowlette, R.A.M.C., attached to the Irish Guards.
Captain H B Thomason, R.A.M.C.
Lieutenant G J Fraser, R.A.M.C., attached to the Northumberland Fusiliers.
Captain H N Goode, R.A.M.C.
Captain A Hamilton, R.A.M.C., attached to the West Yorkshire Regiment.
Captain C A Bernard, R.A.M.C., attached to the York and Lancaster Regiment.
Captain T W David, R.A.M.C.
Lieutenant C B Davies, R.A.M.C.
Captain L D Shaw, R.A.M.C.
Captain J A Cole, R.A.M.C.
Captain P Walsh, R.A.M.C., attached to the Royal Welsh Fusiliers.
Captain R M Miller, R.A.M.C., attached to the Royal Welsh Fusiliers.
Captain W A Coats, R.A.M.C., attached to the Essex Regiment.
Lieutenant M G Pettigrew, R.A.M.C., attached to the Welsh Regiment.
Captain F Sanders, R.A.M.C., attached to the Essex Regiment.
Captain H P Whitworth, R.A.M.C.
Captain W K Campbell, R.A.M.C.
Captain F E Chapman, R.A.M.C., attached to the Royal West Kent Regiment.
Captain S W McClellan, R.A.M.C.
Lieutenant M McNiff, R.A.M.C., attached to the Middlesex Regiment.
Captain J P Charles, R.A.M.C., attached to the Highland Light Infantry.
Captain D H Derry, R.A.M.C., attached to the King's Royal Rifle Corps.
Captain D J Evans, R.A.M.C.
Captain C F Hacker, R.A.M.C., attached to the Hertford Regiment.
Captain F W A Ponsford, R.A.M.C., attached to the East Surrey Regiment.
Captain C R Wills, R.A.M.C., attached to the Sherwood Foresters.

Previously reported Missing now reported Prisoner

Captain W R W Haight, Canadian A.M.C., attached to the Canadian Mounted Rifles.

OBITUARY OF THE WAR

JOHN CECIL RIX, M.R.O.S. ENG.,
CAPTAIN ROYAL ARMY MEDICAL CORPS.

Captain J. C. Rix, who was killed in action in France on the night of July 5th-6th at the age of 40, was the fourth son of the late William Howells Rix, of Tunbridge Wells. From Tonbridge School he entered Trinity College, Cambridge, graduating B.A. in 1898, and continued his medical studies at the Middlesex Hospital, qualifying M.R.O.S. in 1902. He then joined his father and uncle in practice at Tunbridge Wells, where he became medical officer to the Convalescent Home and to the Invalid Children's Aid Association. He also acted for a time as medical officer of health and was police surgeon and school medical officer. He was much liked by the police of the town, who made him a presentation when he gave up this appointment. Captain Rix joined the Royal Army Medical Corps in April, 1915, and was gazetted captain a year later. He

met his death from the effects of a shell explosion while he was attending to the wounded outside his first-aid station. His kindly disposition and genial manners had made him a general favourite in both official and social life, and his death is much deplored by his comrades. Captain Rix was unmarried.

GEORGE OLIVER MAW, M.R.O.S. ENG.,
CAPTAIN ROYAL ARMY MEDICAL CORPS.

Captain G. O. Maw, who died in France on July 10th, at the age of 29 years from wounds in action, was the only son of George Maw, M.R.O.S., of Shortlands Kent. He was educated at St. Andrew's School, Eastbourne, and at Olferton College, going on to Pembroke College, Cambridge. After taking a first class in the Natural Science Tripos

in 1909 he continued his medical work at St. Bartholomew's Hospital, where his studies were unfortunately interrupted by a very long and serious illness which ended in a successful operation at the hands of Sir Victor Horsley. He passed the Conjoint Examination in 1912, and being prevented by the war from completing his examination for the M.B. Cambridge took appointments as house physician for six months at Bedford County Hospital and as house surgeon for a year at the Metropolitan Hospital.

In January, 1915, he obtained a commission in the R.A.M.C. remaining in France until the time of his death. His fatal wounds were received while attending to injured men in the open and he died on his way to the ambulance.

One of his oldest friends, who was in the same house at school and in the same College at Cambridge, writes of Captain Maw: "I knew him well enough to appreciate his worth, his absolute truthfulness, fine character, and keenness in his work. His pluck was phenomenal, as we all knew long ago at the time of his operation. In dying for his

country he crowns his well spent young life, and we who mourn him will also rejoice that he has done all a man can do."

EDWARD WILLIAM LAWRENCE, M.B., CH.B. EDIN.,
CAPTAIN ROYAL ARMY MEDICAL CORPS.

Captain E. W. Lawrence, who was killed on active service in France on July 10th at the age of 28 years, was the eldest son of Mr. A. J. Lawrence of Pontycymmer, Glamorgan. He was educated at Christ College, Brecon, and University College, Cardiff, and took the medical course at Edinburgh University where he graduated in 1910.

After some experience as assistant in general practice and house appointments at the Royal Gwent Hospital, Newport, he entered into partnership with Mr. Wyndham Randall at Bridgend. On the outbreak of war he volunteered his services and obtained a commission in the Royal Army Medical Corps, becoming senior medical officer to a brigade at Rhyl and then going with the University Battalion to France, where he remained until his death. Fellow officers in writing to his partner describe Captain Lawrence as a general favourite in his mess. He exposed himself freely to danger in the performance of his duties and it is added, "would go anywhere nothing would stop him."

ALEXANDER STANGER SEABROOKE, M.B.,
B.O. CANTAB.,
CAPTAIN ROYAL ARMY MEDICAL CORPS.

Captain A. S. Seabrooke, who died in Mesopotamia on July 1st from typhoid at the age of 31, was the second son of Mr. J. Seabrooke, of Grays, Essex. He was educated at Tonbridge School, where he became head of his house and at Christ's College, Cambridge, entering heartily into the life and spirit of the University. He was a member of
